

## Exercises Week 9

### Longitudinal vibrations of a long elastic rod

Consider the continuum limit equation obtained in Week 6 for the coupled springs, i.e. the Navier-Cauchy equation in one dimension,

$$\frac{1}{c^2} \frac{\partial^2 u(x, t)}{\partial t^2} - \frac{\partial^2 u(x, t)}{\partial x^2} = 0, \quad (1)$$

where  $u$  is the displacement and  $c$  is the speed of sound. We will now solve the equation for a rod of length  $L$  with the boundary conditions

$$\begin{cases} \sigma_{xx}(L, t) = 0 \\ u(0, t) = 0 \\ \left. \frac{\partial u}{\partial t} \right|_{t=0} = 0 \\ u(x, 0) = \alpha x \end{cases} \quad (2)$$

- 1) Explain what these boundary conditions mean physically. Is the rod initially strained? How is it fixed in space?

We will try to find a solution by separation of variables, that is a solution on the form

$$u(x, t) = T(t)X(x). \quad (3)$$

- 2) By inserting the product form in Eq. (1), show that one obtains the two equations

$$\frac{X''}{X} = \frac{1}{c^2} \frac{T''}{T} = -\lambda^2 \quad (4)$$

with a separation constant  $\lambda$ .

- 3) Show next that the full solution that satisfies the boundary conditions assumes the form

$$u(x, t) = \sum_n A_n \cos(\lambda_n ct) \sin(\lambda_n x), \quad (5)$$

where

$$\lambda_n = \left( \frac{1}{2} + n \right) \frac{\pi}{L} \quad (6)$$

For  $t = 0$ , we obtain from the boundary condition, the following equation for the coefficients  $A_n$

$$\alpha x = \sum_n A_n \sin(\lambda_n x), \quad (7)$$

- 4) Find the coefficients  $A_n$  (how well do you remember the Fourier-transformation?? ;) and plot the solution by truncating the sum Eq. (5) at a finite  $n$ . The coefficients should be

$$A_n = \frac{2\alpha(-1)^n L}{\pi^2(1/2 + n)^2}$$

## Radial vibration of a linear elastic sphere

Find the characteristic frequencies for the radial vibrations of a linear elastic sphere in vacuum. Note that for radial vibrations, the displacement field is rotation free and can therefore be written as the gradient of a scalar field  $\varphi(r, t)$ , i.e.

$$\mathbf{u}(r, t) = \nabla\varphi(r, t) = \partial_r\varphi(r, t)\mathbf{e}_r \quad (8)$$

You can further assume  $\varphi(r, t)$  can be written on product form

$$\varphi(r, t) = f(r)e^{i\omega t} \quad (9)$$

Since the sphere is assumed to vibrate in vacuum there will be no stresses acting from the outside on the sphere, that is use the boundary condition

$$\sigma_{rr}(a) = 0, \quad (10)$$

where  $a$  is the radius of the sphere. Note that you could as well solve directly the radial-symmetric Navier-Cauchy equation without introducing the auxiliary scalar field  $\varphi$ .

## Exercises from the book

12.8, 12.10, 24.1, 24.4, 24.6
