Applied Statistics Simpson's Paradox

Troels C. Petersen (NBI)

"Statistics is merely a quantisation of common sense"

In 1973, University of California, Berkeley, were considering which of their applicants got admitted.

As can be seen below, there is seemingly a **bias against women**, as a smaller fraction of women are admitted.

Is that really the case, or is there more to the data than first glance reveals?

In 1973, University of California, Berkeley, were considering which of their applicants got admitted.

As can be seen below, there is seemingly a **bias against women**, as a smaller fraction of women are admitted.

Is that really the case, or is there more to the data than first glance reveals?

Sex Bias in Graduate Admissions: Data from Berkeley

Measuring bias is harder than is usually assumed, and the evidence is sometimes contrary to expectation.

Table 1. Decisions on applications to Graduate Division for fall 1973, by sex of applicant naive aggregation. Expected frequencies are calculated from the marginal totals of the observed frequencies under the assumptions (1 and 2) given in the text. N = 12,763, $\chi^2 = 110.8$, d.f. = 1, P = 0 (18).

Applicants		Outo	Difference			
	Observed				Expected	
	Admit	Deny	Admit	Deny	Admit	Deny
Men	3738	4704	3460.7	4981.3	277.3	- 277.3
Women	1494	2827	1771.3	2549.7	- 277.3	277.3

Men Women	3738 1494	4704 2827	3737 / (3738- 1494 / (1494-	+4704) = 4 +2827) = 3	4.3% 277.3 34.6% 277.3	- 277.3 277.3		

Bickel et al. goes on to analyse the data further with several interesting findings:

sex. Our computations, therefore, except where otherwise noted, will be based on the remaining 85. For a start let us identify those of the 85 with bias sufficiently large to occur by chance less than five times in a hundred. There prove to be four such departments. The deficit in the number of women admitted to these four (under the assumptions for calculating expected frequencies as given above) is 26. Looking further, we find six departments biased in the opposite direction, at the same probability levels; these account for a deficit of 64 men.

Out of 85 departments with relevant data, a few seem to show a bias... in both directions, and mostly agains men!!! What!

This seems counter intuitive to what we found to begin with. Where did the bias of 277 women less than expected go?

The deficit in the number of women admitted to these four (under the assumptions for calculating expected frequencies as given above) is 26. Looking further, we find six departments biased in the opposite direction, at the same probability levels; these account for a deficit of 64 men.

Out of 85 departments with relevant data*, a few seem to show a bias... in both directions, and mostly agains men!!! What!

This seems counter intuitive to what we found to begin with. Where did the bias of 277 women less than expected go?

*Here you should ALWAYS ask, what this involves! In this case, 16 departments either had no women applying, or did not deny any students admission.

In order to illustrate the point, Bickel et al. gives a hypothetical (and fun!) case:

Table 2. Admissions data by sex of applicant for two hypothetical departments. For total, $\chi^2 = 5.71$, d.f. = 1, P = 0.19 (one-tailed).

Applicants		Out	Difference			
	Observed				Expected	
	Admit	Deny	Admit	Deny	Admit	Deny
		Departm	ent of machis	matics		4944994949444444949 4 44944944944944944944944
Men	200	200	200	200	0	0
Women	100	100	100	100	0	0
		Departm	ent of social v	varfare		
Men	50	100	50	100	0	0
Women	150	300	150 Totals	300	0	0
Men	250	300	229.2	320.8	20.8	- 20.8
Women	250	400	270.8	379.2	- 20.8	20.8

The two (very hypothetical) departments are clearly very fair regarding gender, but still a difference appears between the overall resulting observation and expectation.

The "apparent conclusion" (Berkeley discriminates against applications from women) is a result of Simpson's Paradox (my text):

"Effect for group, which disappears or reverses, when considering subgroups".

It is effects such as this, which makes statistics difficult, yet at the same time **very important**.

different degree. The proportion of women applicants tends to be high in departments that are hard to get into and low in those that are easy to get into. Moreover this phenomenon is more pronounced in departments with large numbers of applicants. Figure 1

Fig. 1. Proportion of applicants that are women plotted against proportion of applicants admitted, in 85 departments. Size of box indicates relative number of applicants to the department.

Simpson's Paradox explained

The reason for the **apparent** paradox arise when frequency data is unduly given causal interpretations.

The figure on the right illustrates the "paradox" nicely.

The situation can be illustrated with 2D vectors, as shown below.

A succes rate p/q (successes / attempts) can be represented by vectors with a slope. Higher slope = higher succes rate.

But though B1 is steeper than L1, and B2 is steeper than L2, then B1+B1 is not as steep as L1+L2.
