Big Data Analysis

Data set: Housing Prices

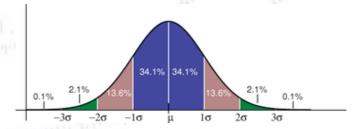

Troels C. Petersen (NBI)

"Statistics is merely a quantisation of common sense - Machine Learning is a sharpening of it!"

Data, goal, and misc.

The data:

About **50.000 real estate sales**, including the final sales price along with several descriptive variables, many incomplete or missing.

The goal:

To determine the final sales price as accurately as possible.

NOTE: "As accurately" is not a well determined measure, and we will discuss this.

Miscellaneous:

While the dataset is on the border of "Big Data", we have chosen it, as it fits all the ML methods well, and since its analysis can be **done in finite time**.

Information available

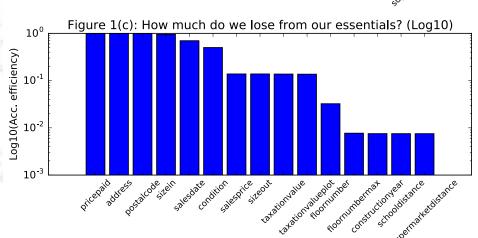

While there are in principle 90 pieces of information on each property sale, it is in practice not the case! As it turns out, most entries are empty!!!

In the figure we consider the most crucial variables (see page before), and check what fraction of entries have information available here.

The conclusions is, that if we wanted all entries filled, we would only have < 1% of data remaining... not a great way forward!

Information

availa

In the figure we consider crucial variables (see parcheck what fraction of einformation available h

The conclusions is, that all entries filled, we wo which is a fair < 1% of data remaining... not a great

way forward!

One could choose to require that e.g. the first six variables are valid, and then only add the ones with (almost) full availability:

0.8

fficiency 0.6

- Price paid (of course)
- Address
- Postal Code
- Size inside
- Sales date
- Condition
- Size outside
- Taxation value
- Floor number
- School distance
- Supermarket distance

This leaves about 50% of the data, which is a fair choice...

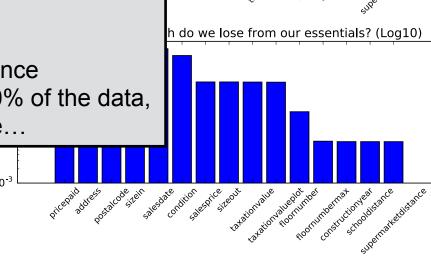

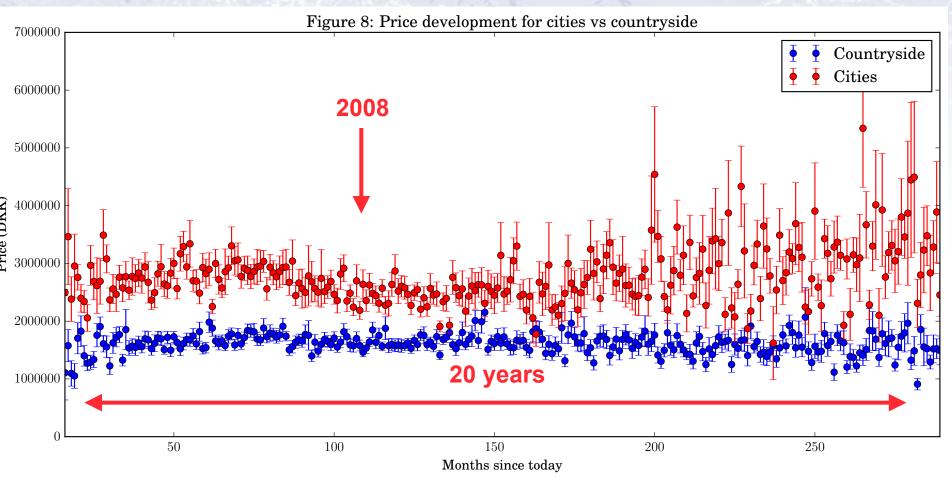

Figure 1(a): Is the info there?

ratation value

much do we lose from our essentials?

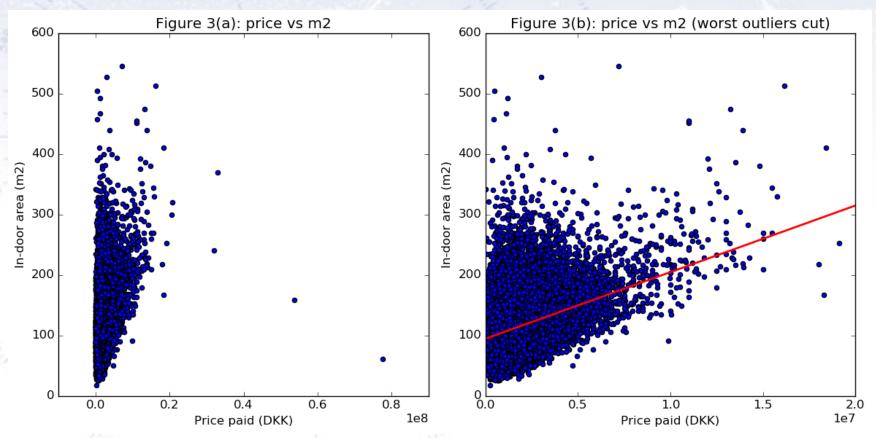

Price vs. time

Just to gauge the data, we try to plot the average price over time:

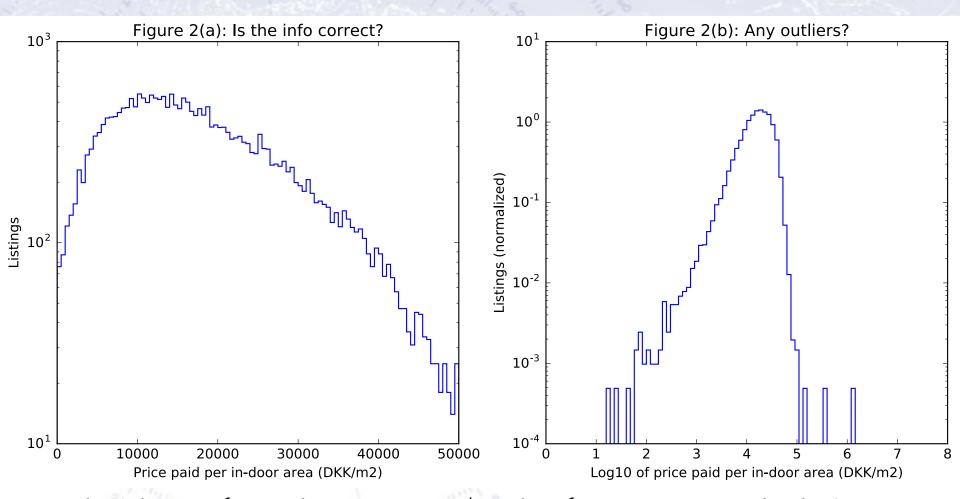

Clearly, the data is corrected for inflation, but not much else, since 2008 doesn't clearly show up.

As a first step, one would estimate the price from the size, i.e. assume that the price per square meter was constant, and so we plot price vs. size:

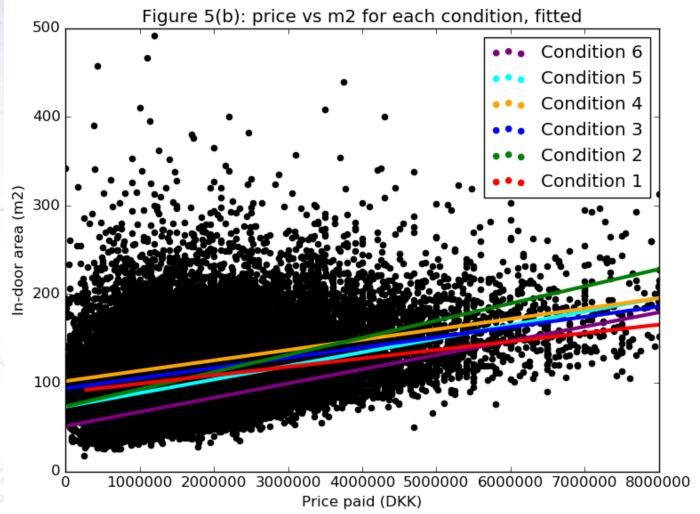

As can be seen from the figure, this does not seem to be the case, and even after filtering away the worst outliers, we don't get any reasonable estimate!

Looking at the price/m2, most values are reasonable, but there are exceptions:

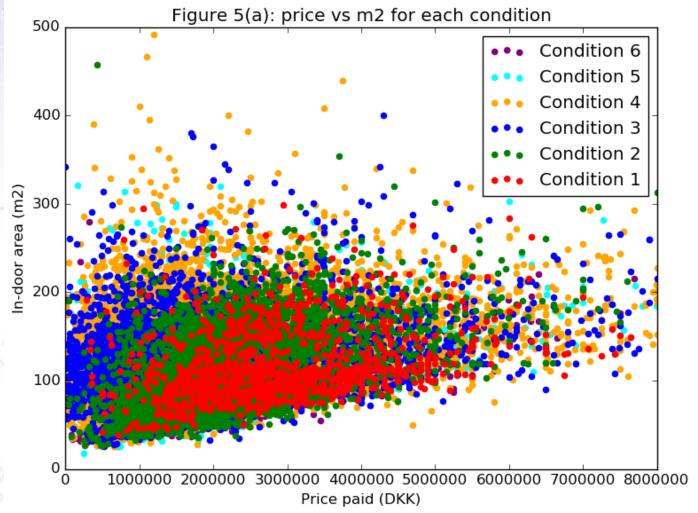

I don't know who paid 1.000.000+ Kr./m2, but that is not a normal value! Similarly, < 100 Kr./m2 seems odd, and also needs further investigation.

Dividing according to condition, one might expect a higher price/m2, but...

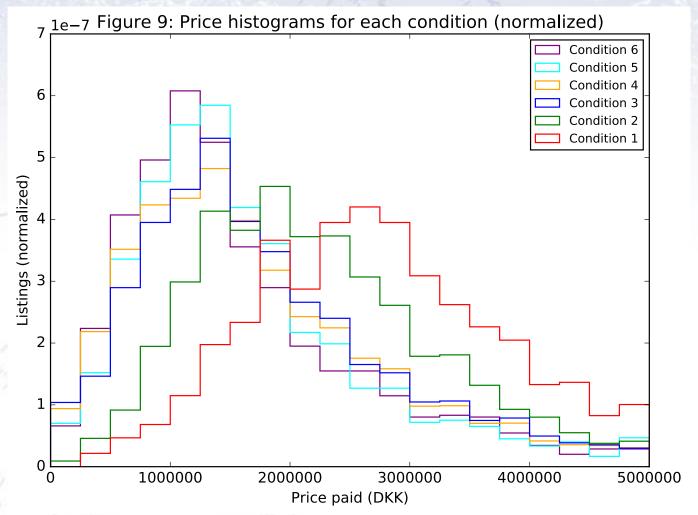

...the pattern is rather, that the basic price is higher!

Dividing according to condition, one might expect a higher price/m2, but...

...the pattern is rather, that the basic price is higher! And condition 1 is best!!!

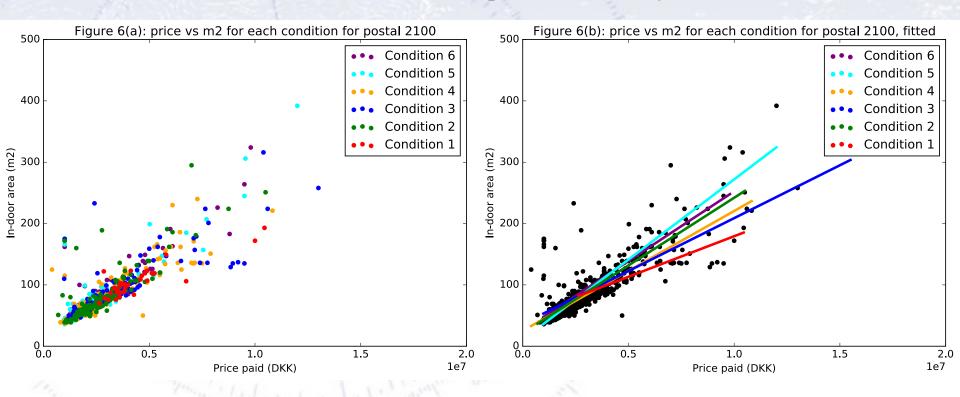

Dividing according to condition, one might expect a higher price/m2, but...

...the pattern is rather, that the basic price is higher! And condition 1 is best!!!

Considering Østerbro only

If we restrict ourselves to Østerbro, the pattern suddenly becomes more clear:

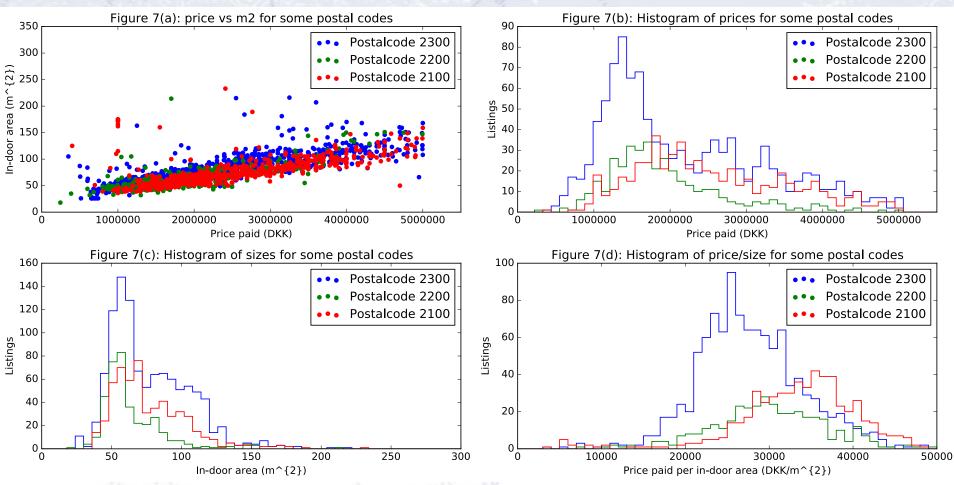

The number of square meters suddenly become a much better indicator, and a condition suddenly also becomes a better variable.

So clearly, district/postal code is also a factor, as should be no surprise.

Comparing districts

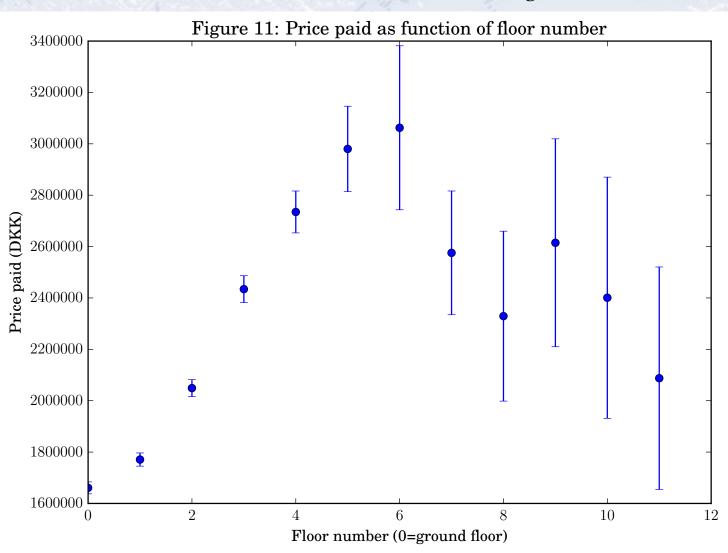

Now we consider the various postal codes (Østerbro, Nørrebro og Amager):

Amager has small apartments and lower price/m2, and the linear model (price = price/m2 * size) holds OK for each district.

Floor vs. price

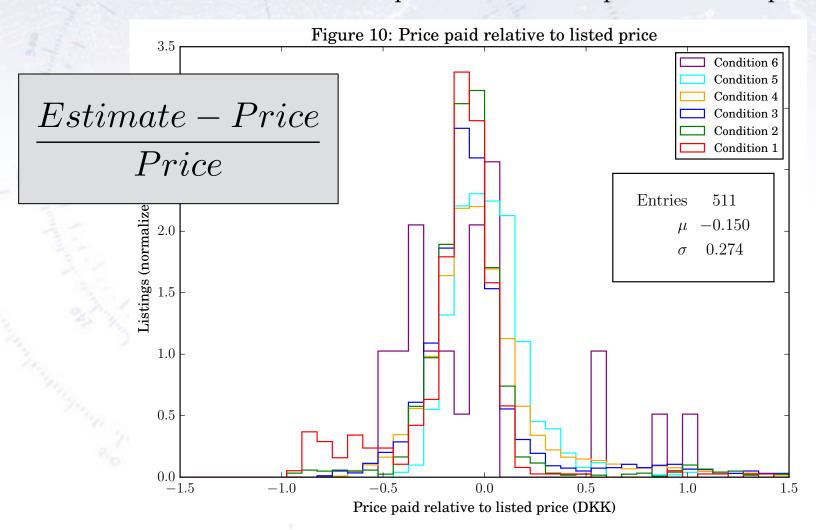

One can continue with all sorts of variables, such as e.g. floor:

A "measure-of-goodness"

Q: How do we know, that we are improving our price estimates?

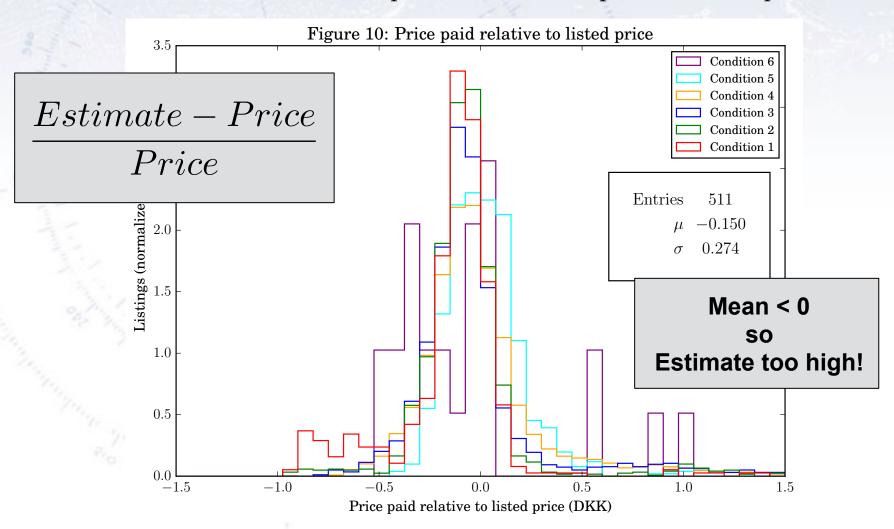

A: Well, consider how close the predictions are compared to actual price.

A "measure-of-goodness"

Q: How do we know, that we are improving our price estimates?

A: Well, consider how close the predictions are compared to actual price.

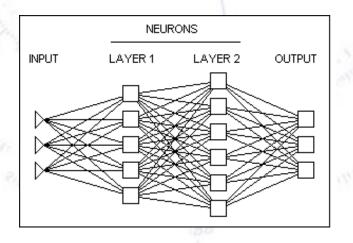

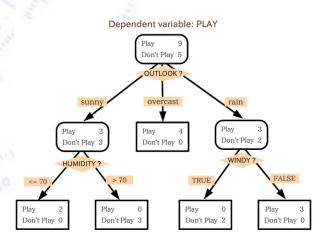

The path forward

Clearly, we could continue in this way, and produce a more and more refined model, which would give a rough estimate for most cases, but...

- The model gets more and more complicated to update or improve.
- There is no "system" by which the model can be improved.
- The process is very manpower intensive.

The solution is of course to use MultiVariate Analysis (MVA) on large datasets (which essentially is Big Data analysis), which in an automated and often very powerful way can combine many variables into one "optimal" prediction (or separation, if categorising).

Discussion of path forward

Which considerations do you have in mind regarding doing an MVA approach?

- Data size and splitting.
- Current and potential input variables.
- ML algorithms.
- Loss function.
- Output(s).

Discuss first with your collaborators (5 min), and then we'll do it in plenum.
