Bayesian Methods, Population Mixtures

Adriano Agnello

12th May 2021

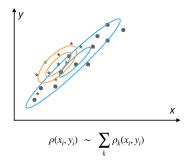

This is a chunky lecture, with some extra stuff if you want to go see it afterwards. We'll see:

- What's all this *Bayesian* stuff that people talk about?!
- Why best-fit is not always the best, and what you can do about it.
- How we can fit a distribution without binning the data (a.k.a. *binning is sinning*).
- Another *unsupervised* learning method for clustering, with some sklearn help of course.

Mixture Models

Let's consider a swarm of points $\mathbf{x}_{i=1,...,N} \in \mathbb{R}^{p}$...

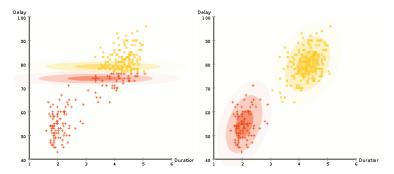

...and a model $\rho(\mathbf{x})$ for how they should be distributed.

< < >> < <</p>

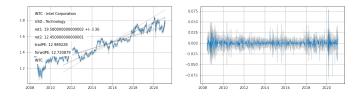

Expectation-Maximisation

In a nutshell: similar to k-means iterations, but it also adjusts the shape and relative weight of the clusters.

Bonus: HMM

NB: Today we'll deal with mixture models for points that are all drawn independently from each other! This is not always the case, e.g.

In financial time series, the correlated behaviour of $\delta \log(price)$ is well known (e.g. "volatility clustering").

There are ways to generalize mixture models and EM to this case, e.g. Hidden Markov Models.

(we won't see them today, but a fun example of final project!)

OK, let's start with the Bayesian stuff...

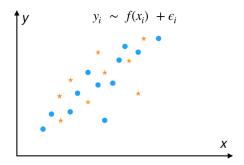

▶ ∢ ≣

크

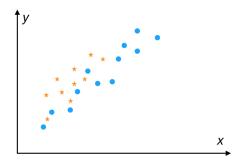

Case 0: fit a line through some points. Minimize the chi-squared

$$\chi^2 = \sum_{i=1}^{N} \frac{(y_i - f(\mathbf{x}_i; \boldsymbol{\theta}))^2}{\epsilon_i^2}$$
(1)

with respect to some parameters (θ).

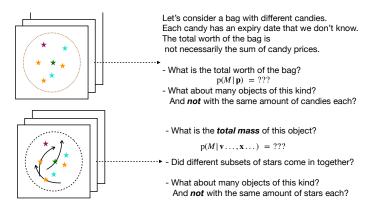

But what if the points have some intrinsic scatter around $f(\mathbf{x})$? What if they come from different populations? What about measurement errors on the \mathbf{x}_i ?

Answer: go Bayesian.

Case 1: cases where you have *latent* variables, non-fixed dimensionality, and need to guess a complicated regression.

Answer: go Bayesian.

What's with that P(A|B)

Probability: a measure¹ on a space of events \mathcal{E} , with $P(\mathcal{E}) = 1$. Conditional probability:

$$P(A|B) := P(A \cap B)/P(B)$$
⁽²⁾

Then

$$P(B)P(A|B) = P(A \cap B) = P(A)P(B|A)$$
(3)

This is Bayes' Thorem.

E.g.: think of a thermostat that goes on *mostly* when $T > 28^{\circ}$ C and is off *mostly* when $T < 28^{\circ}$ C... If it turns on (and I don't have a thermometer), what are the odds that it's actually hot and not a glitch?

¹Sigma-additive, positive-definite, null on empty subset...

What's with that P(A|B)

Probability: a measure¹ on a space of events \mathcal{E} , with $P(\mathcal{E}) = 1$. Conditional probability:

$$P(A|B) := P(A \cap B)/P(B)$$
⁽²⁾

Then

$$P(B)P(A|B) = P(A \cap B) = P(A)P(B|A)$$
(3)

This is Bayes' Thorem.

E.g.: think of a thermostat that goes on *mostly* when $T > 28^{\circ}$ C and is off *mostly* when $T < 28^{\circ}$ C... If it turns on (and I don't have a thermometer), what are the odds that it's actually hot and not a glitch?

Bayes, models, and data

In terms of data and models: how much would you bet on a model, given observed data?

$$d\mu_{\text{post.}}(\mathbf{m}|\mathbf{d}) \propto \mathcal{L}(\mathbf{d}|\mathbf{m}) d\mu_{\text{pr.}}(\mathbf{m})$$
(4)

< □ > < □ > < □ > < □ >

I.e. given some model parameter values, how likely am I to obtain the observed dataset ($\mathcal{L}(d|m)$)?

NB The model parameters need not be fixed, they may have some *prior* probability measure. This, together with the likelihood ($\mathcal{L}(\mathbf{d}|\mathbf{m})$), gives the *posterior* measure.

NB2 A posterior from a previous measurement can be a prior for a successive (independent) measurement.

Bayes, models, and data

In terms of data and models: how much would you bet on a model, given observed data?

$$d\mu_{\text{post.}}(\mathbf{m}|\mathbf{d}) \propto \mathcal{L}(\mathbf{d}|\mathbf{m}) d\mu_{\text{pr.}}(\mathbf{m})$$
(4)

A D b A A b A b

I.e. given some model parameter values, how likely am I to obtain the observed dataset $(\mathcal{L}(d|m))$?

NB The model parameters need not be fixed, they may have some *prior* probability measure. This, together with the likelihood $(\mathcal{L}(\mathbf{d}|\mathbf{m}))$, gives the *posterior* measure.

NB2 A posterior from a previous measurement can be a prior for a successive (independent) measurement.

Example 1: Given *N* independent points $x_{i=1,...,N}$ on a line, and suppose that each of them is drawn from a Gaussian $\mathcal{G}(x_i - \mu, \sigma)$, where μ and σ are the unknowns that we want to work out. Our likelihood is "simply"

$$\mathcal{L}(\mathbf{x}|\boldsymbol{\theta}) = \prod_{i} \mathcal{G}(\mathbf{x}_{i} - \mu, \sigma) \propto \exp\left(-\frac{1}{2} \frac{\sum_{i} (\mathbf{x}_{i} - \mu)^{2}}{\sigma^{2}}\right)$$
(5)

Q: what are the most likely mean μ and dispersion σ ? $\partial_{\mu}\mathcal{L} = 0 \Rightarrow \mu = \frac{1}{N}\sum_{i} x_{i}$ $\partial_{\sigma}\mathcal{L} = 0 \Rightarrow \sigma^{2} = \frac{1}{N}\sum_{i} (x_{i} - \mu)^{2}$

イロト イ押ト イヨト イヨト

Example 1: Given *N* independent points $x_{i=1,...,N}$ on a line, and suppose that each of them is drawn from a Gaussian $\mathcal{G}(x_i - \mu, \sigma)$, where μ and σ are the unknowns that we want to work out. Our likelihood is "simply"

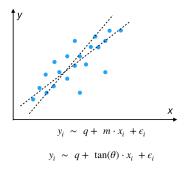

$$\mathcal{L}(\mathbf{x}|\boldsymbol{\theta}) = \prod_{i} \mathcal{G}(\mathbf{x}_{i} - \mu, \sigma) \propto \exp\left(-\frac{1}{2} \frac{\sum_{i} (\mathbf{x}_{i} - \mu)^{2}}{\sigma^{2}}\right)$$
(5)

Q: what are the most likely mean μ and dispersion σ ? $\partial_{\mu}\mathcal{L} = \mathbf{0} \Rightarrow \mu = \frac{1}{N}\sum_{i} x_{i}$ $\partial_{\sigma}\mathcal{L} = \mathbf{0} \Rightarrow \sigma^{2} = \frac{1}{N}\sum_{i} (x_{i} - \mu)^{2}$

A note about Priors

How much of the result is driven by the prior?

Example: fit a straight line through points. Should I write it in terms of slope or in terms of pitch angle?

By the way

Q: so how do I fit a straight line through some points with errors?

If you have points with errors ϵ_x on the x's and ϵ_y on the y's, you can work out the likelihood and it's:

$$\mathcal{L} = \prod_{i} \frac{1}{\sqrt{2\pi(\epsilon_{y,i}^{2} + m^{2}\epsilon_{x,i}^{2})}} \exp\left(-\frac{(y_{i} - mx_{i} - q)^{2}}{2(\epsilon_{y,i}^{2} + m^{2}\epsilon_{x,i}^{2})}\right)$$
(6)

NB1: if you used a "usual" χ^2 or ODR you can have a biased *m*! **NB2:** fitting *y* vs *x* is very similar to fitting *x* vs *y*, if you do it right!

By the way

Q: so how do I fit a straight line through some points with errors? If you have points with errors ϵ_x on the *x*'s and ϵ_y on the *y*'s, you can work out the likelihood and it's:

$$\mathcal{L} = \prod_{i} \frac{1}{\sqrt{2\pi(\epsilon_{y,i}^{2} + m^{2}\epsilon_{x,i}^{2})}} \exp\left(-\frac{(y_{i} - mx_{i} - q)^{2}}{2(\epsilon_{y,i}^{2} + m^{2}\epsilon_{x,i}^{2})}\right)$$
(6)

NB1: if you used a "usual" χ^2 or ODR you can have a biased *m*! **NB2:** fitting *y* vs *x* is very similar to fitting *x* vs *y*, if you do it right!

< □ > < □ > < □ > < □ >

By the way

(6)

NB1: if you used a "usual" χ^2 or ODR you can have a biased *m*! **NB2:** fitting *y* vs *x* is very similar to fitting *x* vs *y*, if you do it right!

Nested models, evidence tests

Model A is more general than model B, is it to be preferred? Different *evidence tests*:

- (from physics lab. 101) change in χ^2 vs change in d.o.f.
- 2 if $\mathcal L$ is Gaussian in the data, same phrasing as the χ^2 test
- 3 AIC: $2k 2\log(\mathcal{L}_{best})$
- BIC: $\log(N)k 2\log(\mathcal{L}_{best})$
- Solution AIC for small sample sizes: $AIC + 2\frac{k^2+k}{n-k-1}$
- significance test: how many 'sigmas' is the new parameter different from zero?
- **②** Jeffrey's test: compute the evidence $Z = \int \mathcal{L} d\mu_{pr.}(\mathbf{m})$, compare $\log_{10}(Z)$.

• • • • • • • • • • • •

Important to keep in mind

Important bit n.1: It's not just the goodness of fit, we want to know how good a model is and how much it can vary *given the current data*.

Important bit n.2: There are different ways of comparing models, and we typically need to integrate $\mathcal{L}d\mu_{pr.}$

How do we explore the likelihood?

- 'grid search': good when parameter space has few dimensions, par.range is already known, likelihood is 'easy'.
- Monte Carlo, draw random points from prior and save their likelihood, or from uniform prior and save the posterior. Good for obtaining integrated quantities, fast convergence for high-dimensional par.space.
- Markov-Chain Monte Carlo: build a Markov Chain s.t. the final density of points is proportional to the posterior.
- Gibbs sampling: to sample p(a, b), alternate drawing from p(a|b) and p(b|a).
- Optimization (e.g. amoeba, gradient descent), approx. optimization (e.g. EM in GMM).

Modeling Densities

Let's consider a swarm of points $\mathbf{x}_{i=1,...,N} \in \mathbb{R}^{p}$...

...and a model $\rho(\mathbf{x})$ for how they should be distributed.

< □ > < □ > < □ > < □ >

Modeling Densities

Let's consider a swarm of points $\mathbf{x}_{i=1,...,N} \in \mathbb{R}^{\rho}$, and a model $\rho(\mathbf{x})$ for how they should be distributed. Let's split \mathbb{R}^{ρ} in cells of volumes δv_j , each containing n_j points. In each cell, the model predicts $mod_j \approx \rho(\mathbf{x}_j)\delta v_j$ points. Likelihood:

$$\mathcal{L} = \prod_{i=1}^{N} \frac{(\rho(\mathbf{x}_{i})\delta v_{j})^{n_{j}} \mathrm{e}^{-\rho(\mathbf{x}_{j})\delta v_{j}}}{n_{j}!}$$
(7)
$$= \left(\prod_{j} \frac{(\delta v_{j})^{n_{j}}}{n_{j}!}\right) \left(\prod_{j} \rho(\mathbf{x}_{j})^{n_{j}}\right) \exp\left(-\int \rho \mathrm{d}v\right)$$
(8)

< □ > < 同 > < 回 > <

 \Rightarrow Often, what really matters is $\rho(\mathbf{x})$ and its parameters. The bins (δv_i) factor out. *Binning is sinning*.

Modeling Densities

Let's consider a swarm of points $\mathbf{x}_{i=1,...,N} \in \mathbb{R}^{\rho}$, and a model $\rho(\mathbf{x})$ for how they should be distributed. Let's split \mathbb{R}^{ρ} in cells of volumes δv_j , each containing n_j points. In each cell, the model predicts $mod_j \approx \rho(\mathbf{x}_j)\delta v_j$ points. Likelihood:

Let's split \mathbb{R}^{ρ} in cells of volumes δv_j , each containing n_j points. In each cell, the model predicts $mod_j \approx \rho(\mathbf{x}_j)\delta v_j$ points. Likelihood:

$$\mathcal{L} = \prod_{i=1}^{N} \frac{(\rho(\mathbf{x}_{i})\delta v_{j})^{n_{j}} \mathrm{e}^{-\rho(\mathbf{x}_{j})\delta v_{j}}}{n_{j}!}$$
(7)
$$= \left(\prod_{j} \frac{(\delta v_{j})^{n_{j}}}{n_{j}!}\right) \left(\prod_{j} \rho(\mathbf{x}_{j})^{n_{j}}\right) \exp\left(-\int \rho \mathbf{d} v\right)$$
(8)

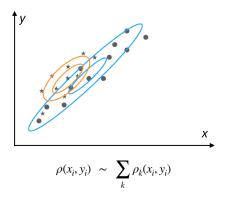

⇒ Often, what really matters is $\rho(\mathbf{x})$ and its parameters. The bins (δv_i) factor out. **Binning is sinning**. **Ex.1:** If $\rho = n_0 \tilde{\rho}$, with $\int \tilde{\rho} dv = 1$, what is the best-fitting n_0 ?

Ex.2: Given *N* points on a line, if we want to draw their histogram, what is the best bin width that we should use?

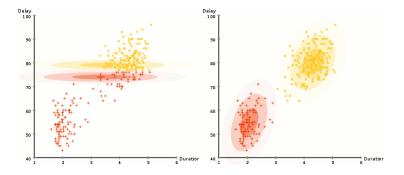

Ex.3: Can you design a way of using histograms with uneven bin-widths?

Ex.4: Given *N* points $x_{i=1,...,N}$ on a line, *if* the model likelihood is $\mathcal{L}(\mathbf{x}|\boldsymbol{\theta}) = \mathcal{G}(\mathbf{x} - \mu, \sigma)$, what are the most likely mean μ and dispersion σ ?

Population Mixtures

Let's consider a *mixture model* $\rho(\mathbf{x}) = \sum_k w_k \tilde{\rho}_k(\mathbf{x})$, with $\int \tilde{\rho}_k \mathbf{d} v = 1$, i.e. we model the swarm of points as drawn from a mixture of blobs $(\tilde{\rho}_k)$, where each blob has a weight (w_k) .

<ロ> <問> <問> < 回> < 回> 、

2

Population Mixtures

Let's consider a *mixture model* $\rho(\mathbf{x}) = \sum_k w_k \tilde{\rho}_k(\mathbf{x})$, with $\int \tilde{\rho}_k \mathbf{d} \mathbf{v} = 1$. Then:

$$\log(\mathcal{L}) = cnst. + \sum_{j} \log\left(\sum_{k} w_{k} \tilde{\rho}(\mathbf{x}_{j})\right) - \sum_{k} w_{k}$$
(9)

The most likely normalizations w_l satisfy $(\partial_{w_l} \log \mathcal{L} = 0)$

$$w_{l} = \sum_{j} \frac{w_{l} \tilde{\rho}_{l,j}}{\sum_{k} w_{k} \tilde{\rho}_{k,j}}$$
(10)

< □ > < □ > < □ > < □ >

This can be solved iteratively.

Q: What about the *internal* parameters of the components $\tilde{\rho}_k$?

NB: We are using blobs, but the points are un-labeled! Labels are *latent variables*.

A finite mixture model has:

- data points $\mathbf{X} = \mathbf{x}_{i=1,...,N} \in \mathbb{R}^{P}$
- (hidden) labels $\mathbf{Z} = z_{i=1,...,N}$
- mixture weights w_{k=1,...,K} and a prior on them
- basis functions $\tilde{\rho}_k$, with some internal parameters

Q: OK but, given the data and the mixture parameters, what are the *most likely* label values?

A: For each point x_i , consider the values $w_k \tilde{\rho}_k(x_i)$ as scores...

A simple Gaussian Mixture Model

Use Gaussian blobs $w_k \tilde{\rho}_k = w_k \mathcal{N}(\mu_k, \mathbf{\Sigma}_k)$.

Everything is simple to write in terms of Gaussians! There is a simple *Expectation-Maximization* algorithm :

$$w_l \mapsto \sum_j \frac{w_l \mathcal{N}_{l,j}}{\sum_k w_k \mathcal{N}_{k,j}}$$
 (11)

$$\boldsymbol{\mu}_{l} \mapsto \sum_{j} \frac{\boldsymbol{w}_{l} \boldsymbol{x}_{j} \mathcal{N}_{l,j}}{\sum_{k} \boldsymbol{w}_{k} \mathcal{N}_{k,j}}$$
(12)

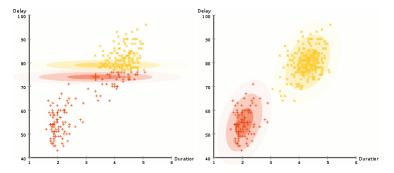

A D b 4 A b

$$\Sigma_{l,\alpha\beta} \mapsto \sum_{j} \frac{w_{l}(x_{j,\alpha} - \mu_{k,\alpha})(x_{j,\beta} - \mu_{k,\beta})\mathcal{N}_{l,j}}{\sum_{k} w_{k}\mathcal{N}_{k,j}}$$
(13)

First line: expectation step. Second and third: maximization step.

The EM is often good enough, if data are well separated and well populated.

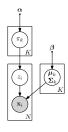

Let's go fully Bayesian...

Bayesian GMM²: priors on the weights and on the averages and covariances. Convenient choices:

- **Dirichlet prior** on the weights $p(\mathbf{w}) \propto \prod_{k=1}^{K} w_k^{\alpha_k-1}$, with hyperparameters α_k .
- Gaussian prior on averages; (inverse) Wishart prior on covariances.

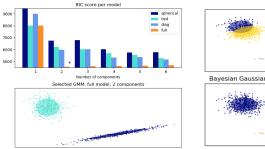

These are useful in order to integrate the posterior over the latent variables.

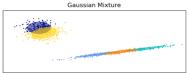

²For the brave:

https://www.kamperh.com/notes/kamper_bayesgmm13.pdf <=> <=> > = <> <<

As for many tools, scikit-learn has a module for it! https://scikit-learn.org/stable/modules/mixture.html Q: How should I choose how many blobs I need for my dataset? (A: try with BIC score... or use Infinite GMM!)

Infinite GMM (Dirichlet process prior).

イロン イ理 とく ヨン イヨン

크

Summing up:

- When we have noisy data or multiple populations, we can go Bayesian.
- Bayesian: how would you bet on a model, given the data at hand?
- posterior = likelihood × prior
- Quantitative ways to control model complexity.
- Sinning is sinning! We can often do without bins (eq.8-9).
- Infinite GMM, Bayesian GMM \rightarrow Infinite GMM.
