

Applied Statistics

Measuring the length of a Table...

Troels C. Petersen (NBI)

"Statistics is merely a quantisation of common sense"

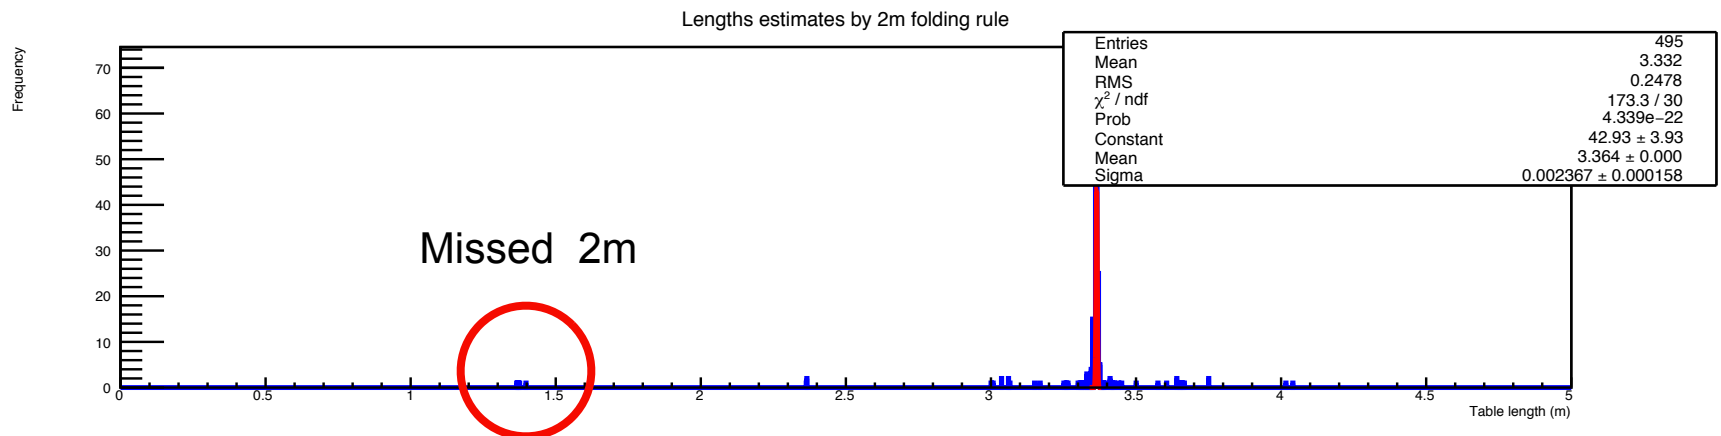

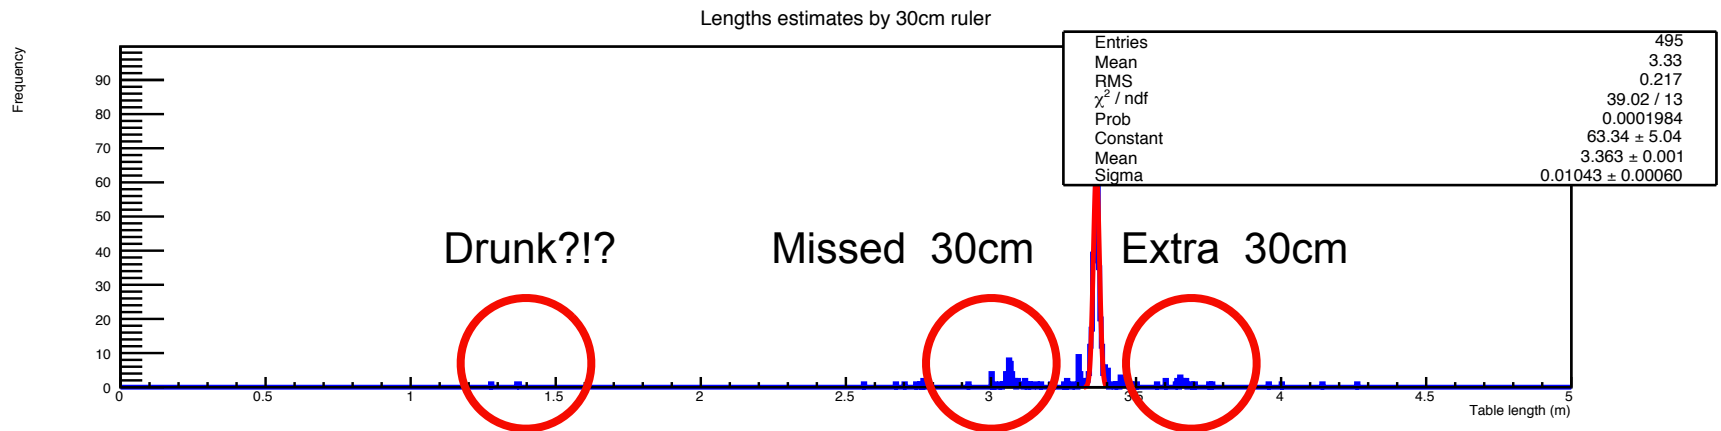

My analysis

The table measurement data

The initial dataset contains (valid measurements):

- 30cm measurements: 495 Range: [0.0, 5.0] m
- 2m measurements: 493 Range: [0.0, 5.0] m

Raw (“Naive”) results

30cm:

Mean = 3.3290 ± 0.0098 m

RMS = 0.22 m (N = 495)

2m:

Mean = 3.3320 ± 0.0112 m

RMS = 0.25 m (N = 493)

Correspondence between 30cm and 2m measurement:

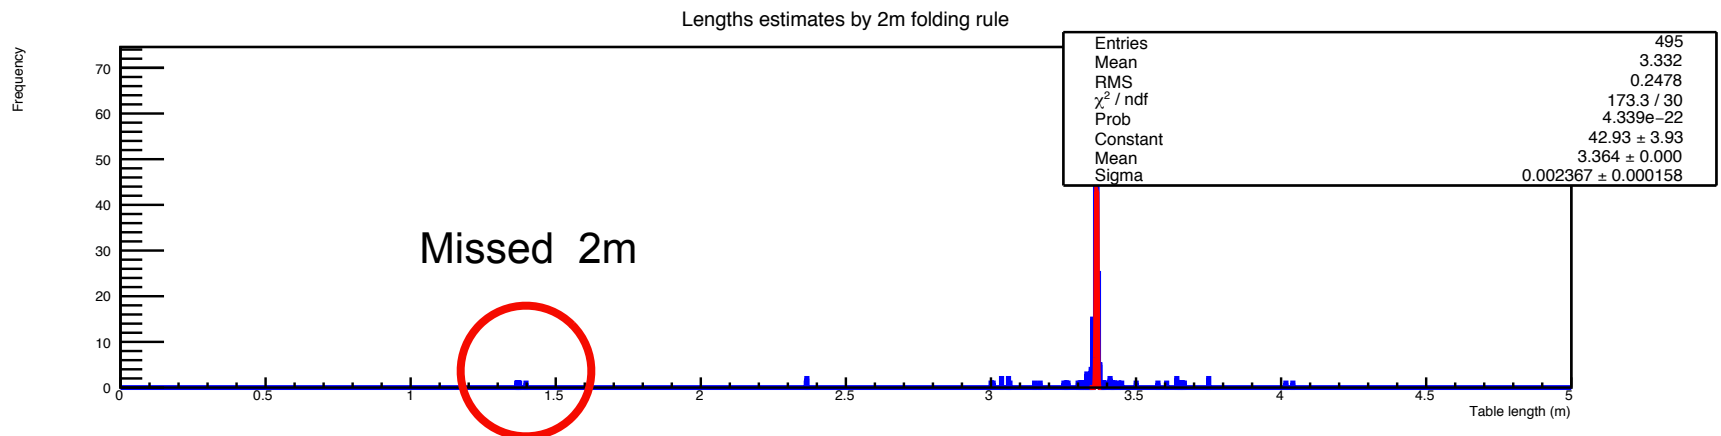

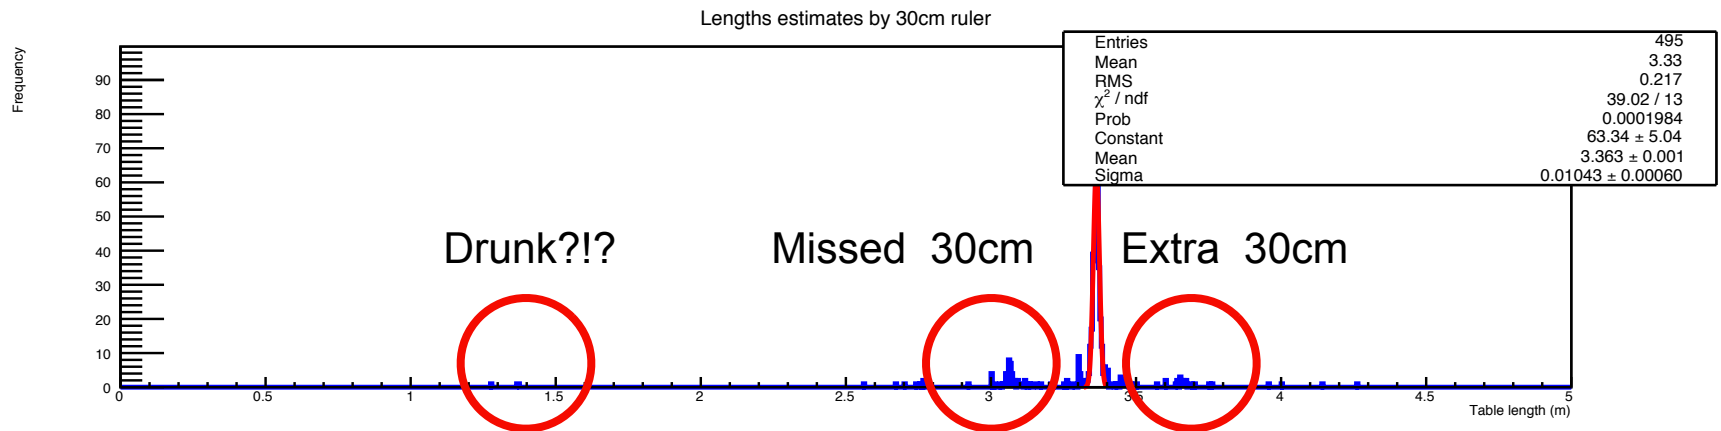

Diff = -0.0030 ± 0.0148 m (-0.20 σ)

Include offsets?

There are some clear and understandable mis-measurements.

Should one correct and include these?

Depends on resulting improvement, but decide without seeing the final result.

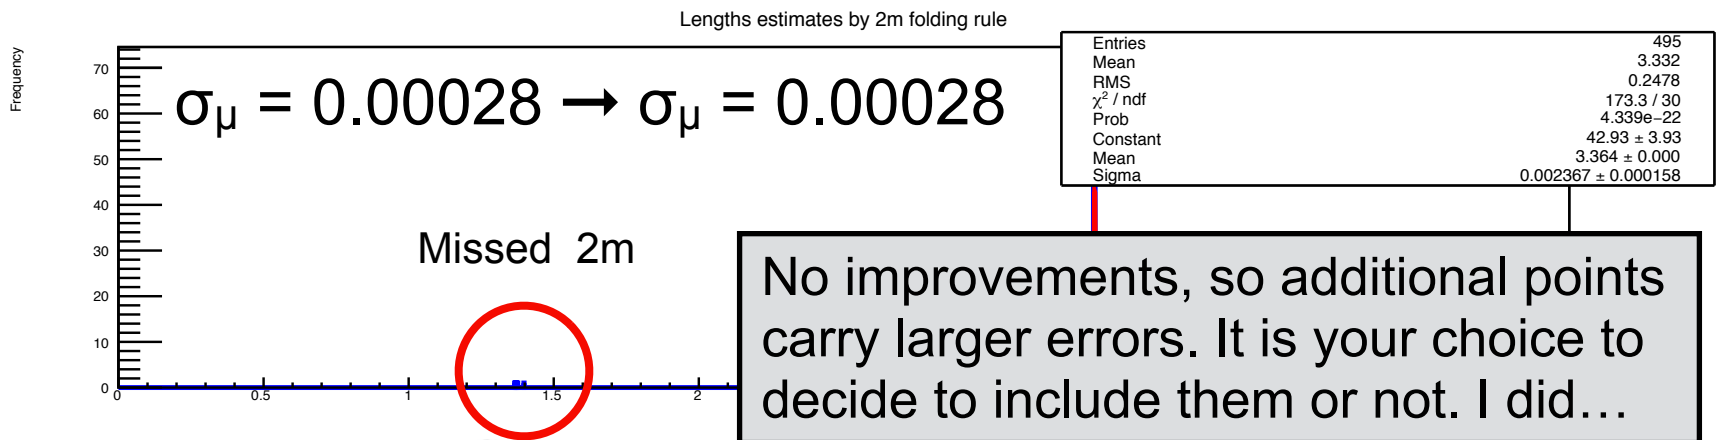

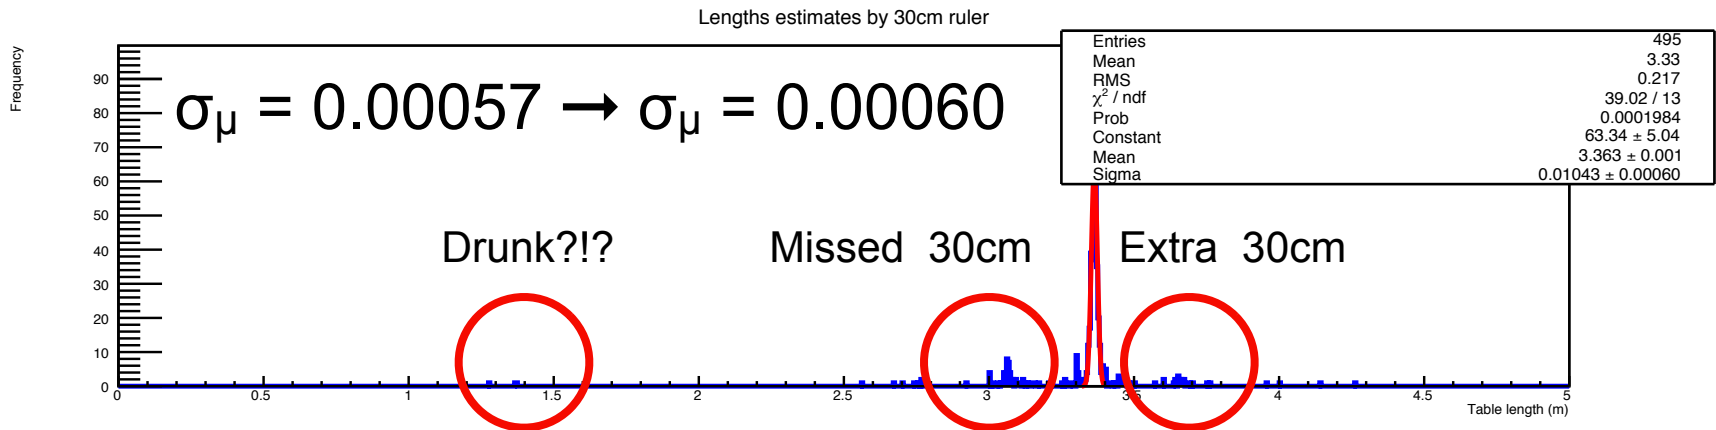

Include offsets?

There are some clear and understandable mis-measurements.

Should one correct and include these?

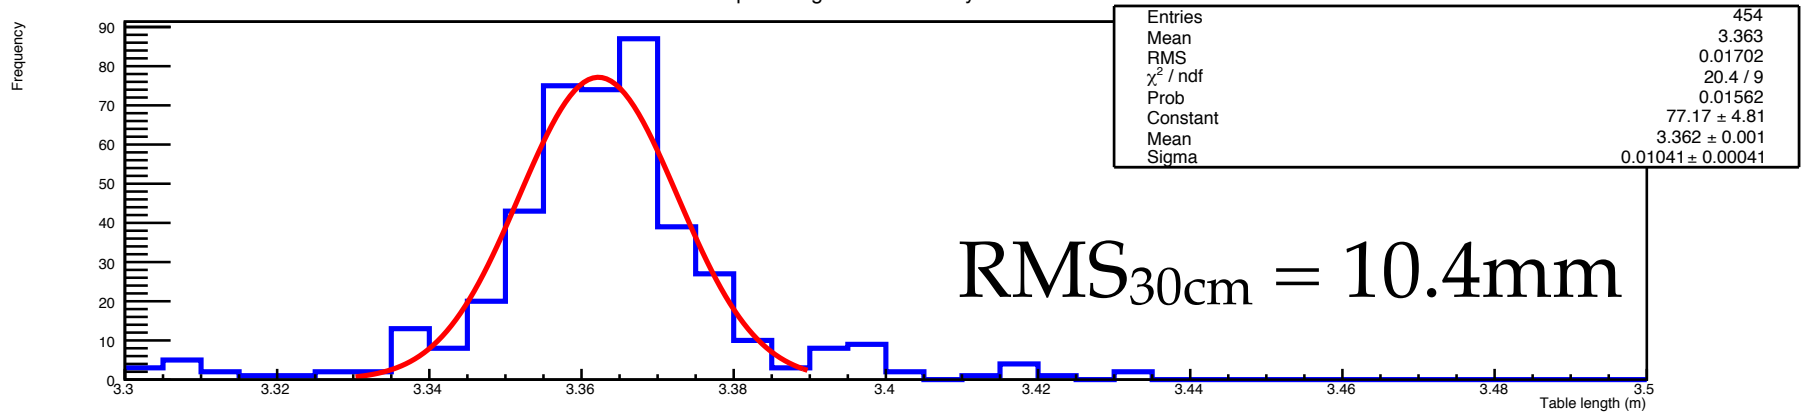

Depends on resulting improvement, but decide without seeing the final result.

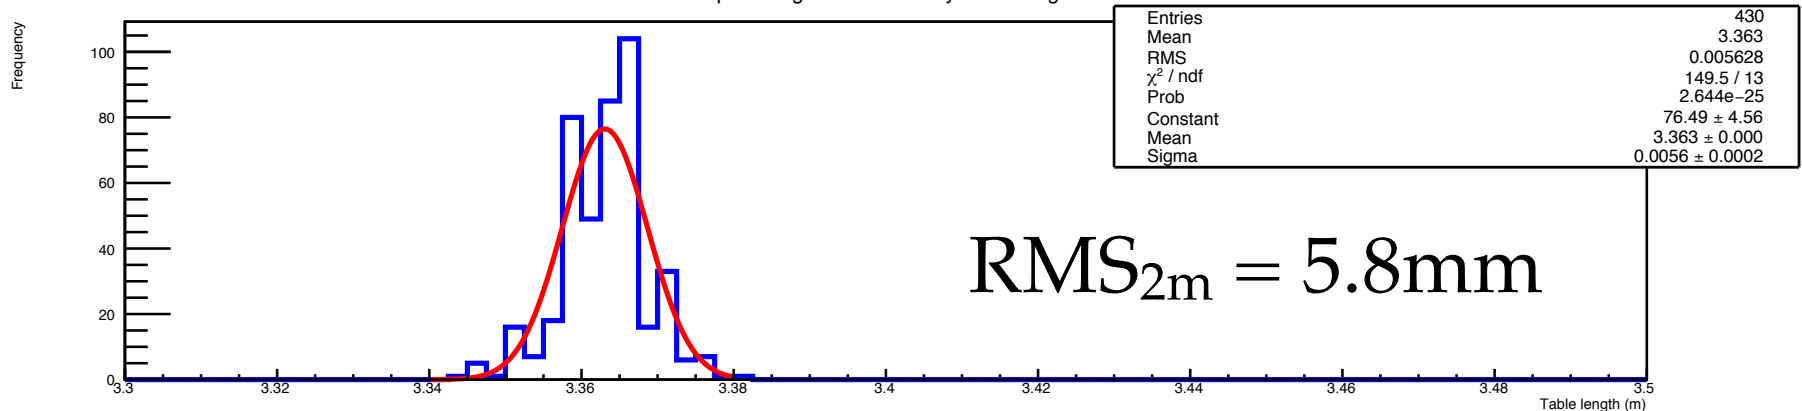

Inspecting the data

The 30cm peak seems Gaussian ($p=2.4\%$) with binning 0.005 (smaller gives peaks).
The 2m peak does not seem Gaussian with any binning (here 0.0025), yet “collected”.

Accepted lengths estimates by 30cm ruler

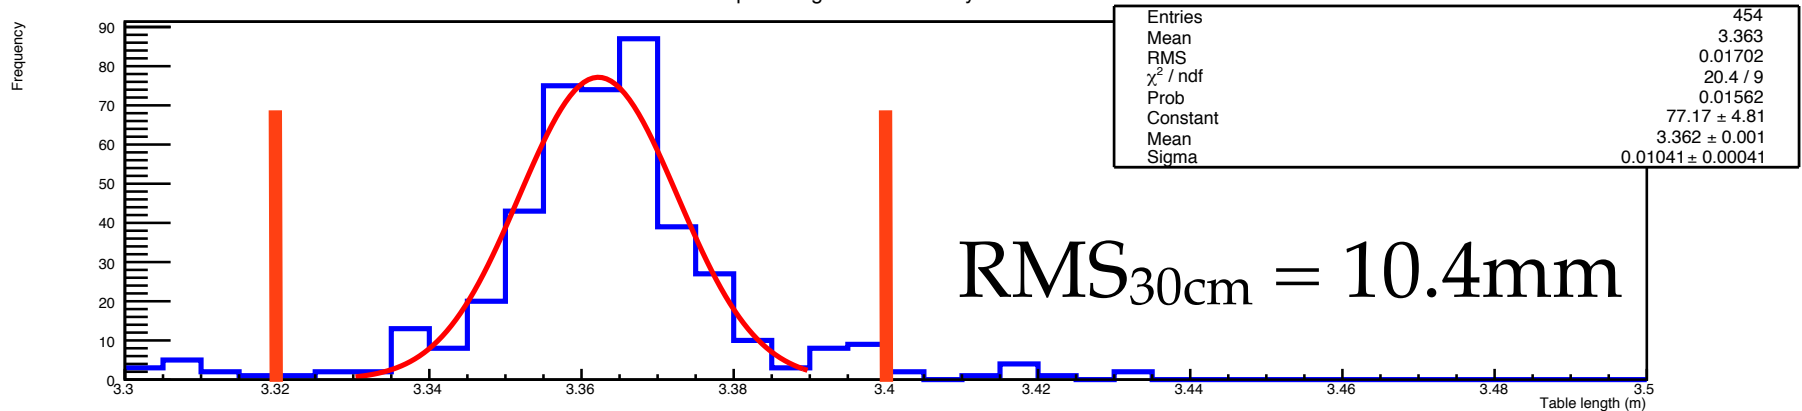

Accepted lengths estimates by 2m folding rule

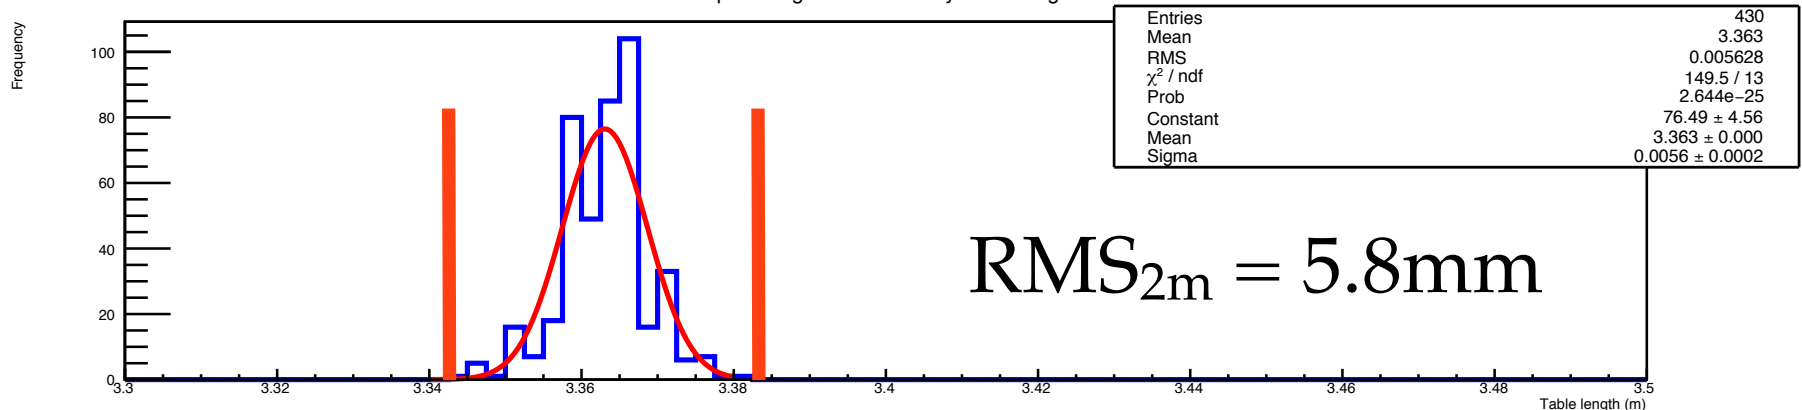

Inspecting the data

There are clearly some **mis-measurements**, which we would like to **exclude**. Using the fitted width, and accepting that this only includes the best measurements, I could **decide** to include measurements within $4 \times \text{RMS}$:

Accepted lengths estimates by 30cm ruler

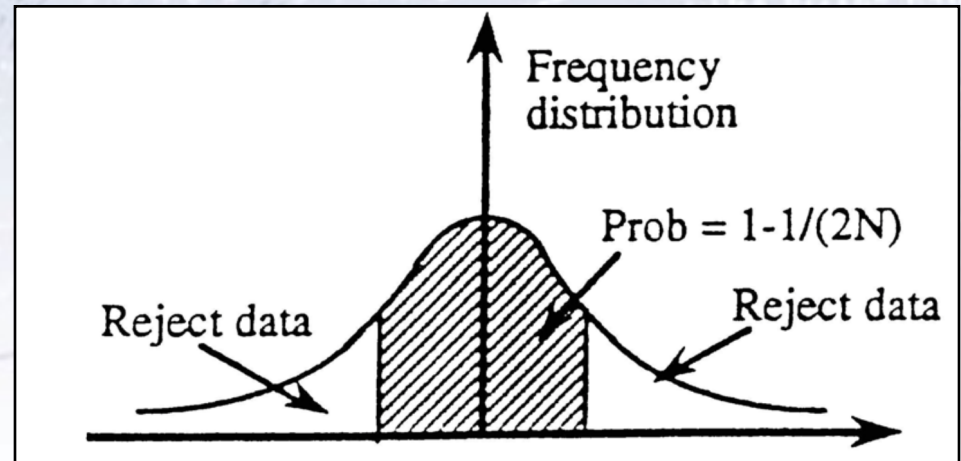

Accepted lengths estimates by 2m folding rule

Removing data points

Removing improbable data points is formalised in **Chauvenet's Criterion**, though many other methods exist (see Peirce, Grubbs, etc.)

The idea is to assume that the distribution is Gaussian, and ask what the probability of the farthest point is. If it is below some value, which is to be determined ahead of applying the criterion, then the point is removed, and the criterion is reapplied until no more points should be removed.

I choose to say, that if the outermost point in the Gaussian case has **less than 5% chance of being this far out** (taking the total number of points into account), then I reject it.

However, **ALWAYS keep a record of your original data**, as it may contain more effects than you originally thought.

...a fair hearing?

Rejected 30cm measurements:

I rejected:
41 data points from the 30cm sample,
63 data points from the 2m sample.
And I inspected each and every one!

Unweighted results

30cm:

Mean = 3.36120 ± 0.00092 m

RMS = 0.020 m (N = 454)

2m:

Mean = 3.36295 ± 0.00026 m

RMS = 0.005 m (N = 430)

Correspondence between 30cm and 2m measurement:

Diff = -0.00175 ± 0.00130 m (-1.35 σ)

With corrections and Chavenet's ($p=0.05$)

Improvement in error from naive to selected measurement 30cm: 10.6

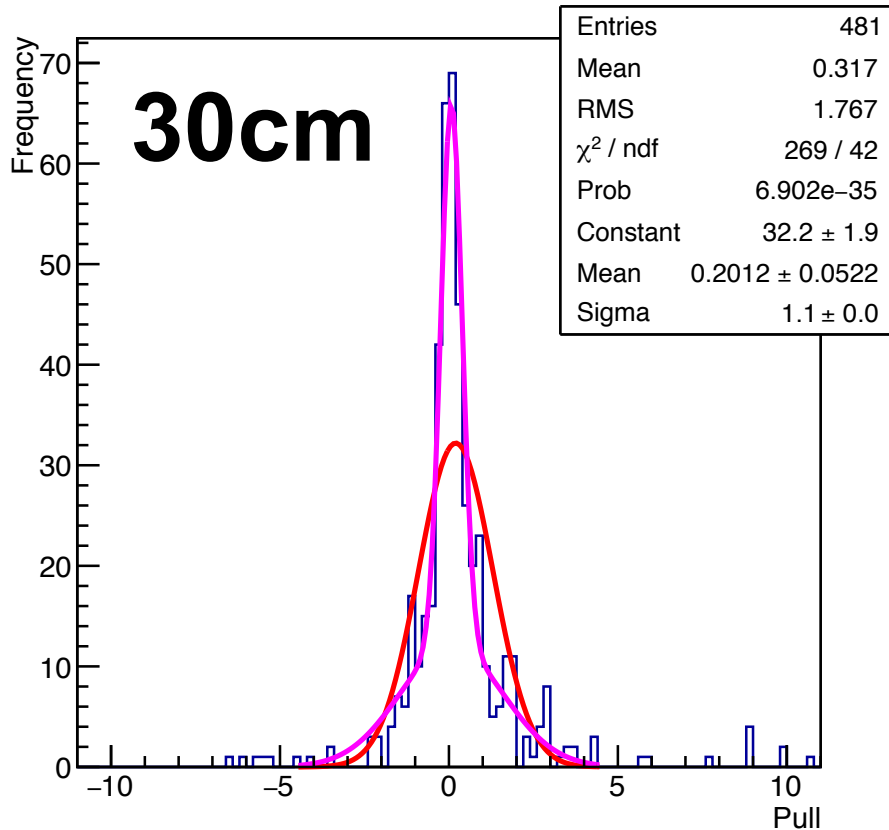

Improvement in error from naive to selected measurement 2m: 42.7

Weighted analysis

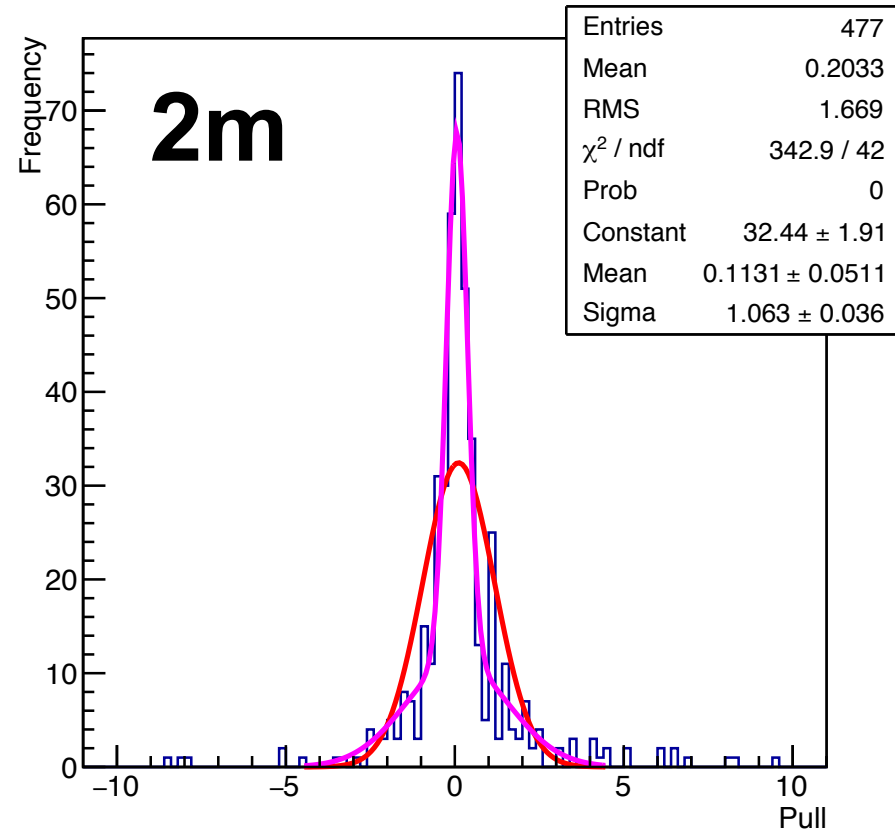

Considering the quoted uncertainties, we first need to evaluate their quality.

The plot to consider is a **PULL** plot, i.e. the distribution of:
$$\mathcal{Z} = \frac{x_i - \mu}{\sigma_i}$$

Pull distribution - 30cm

Pull distribution - 2m

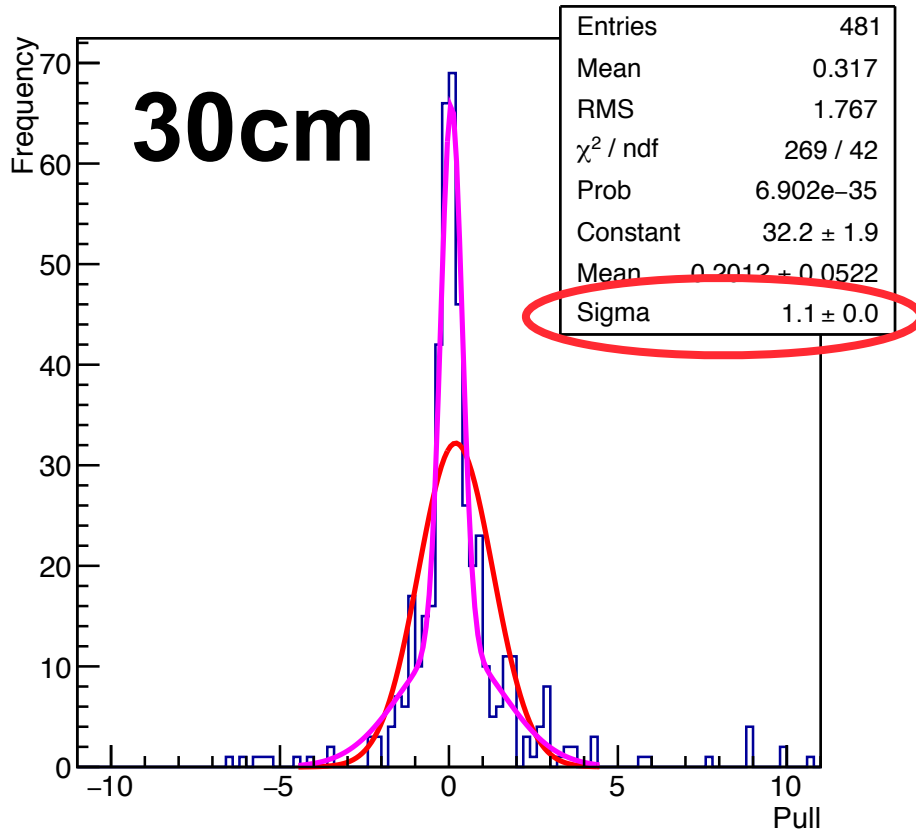

The pulls should be unit Gaussian. I **decide** to exclude measurements beyond 4.5σ .

I rejected:
38 data points from the 30cm sample,
45 data points from the 2m sample.
And I inspected each and every one!

Notice, that close measurement
with too small errors are rejected!

Weighted results

30cm:

Mean = 3.36376 ± 0.00030 m

RMS = undefined! (N = 443)

2m:

Mean = 3.36385 ± 0.00014 m

RMS = undefined! (N = 432)

Correspondence between 30cm and 2m measurement:

Diff = -0.00009 ± 0.00033 m (-0.27 σ)

30cm: $\sigma_{\mu} = 0.00092 \rightarrow \sigma_{\mu} = 0.00030$ (factor 3.1)

2m: $\sigma_{\mu} = 0.00026 \rightarrow \sigma_{\mu} = 0.00014$ (factor 1.8)

Weighted results

30cm:

Mean = 3.36376 ± 0.00030 m

Chi2 = 460.5, N dof = 442, Prob = 0.26

2m:

Mean = 3.36385 ± 0.00014 m

Chi2 = 451.1, N dof = 431, Prob = 0.24

Correspondence between 30cm and 2m measurement:

Diff = -0.00009 ± 0.00033 m (-0.27 σ)

30cm: $\sigma_{\mu} = 0.00092 \rightarrow \sigma_{\mu} = 0.00030$ (factor 3.1)

2m: $\sigma_{\mu} = 0.00026 \rightarrow \sigma_{\mu} = 0.00014$ (factor 1.8)

A problem?

Correspondence: unweighted vs. weighted 30cm measurements:

$$\text{Diff} = 0.00257 \pm 0.00097 \quad (2.65 \text{ sigma})$$

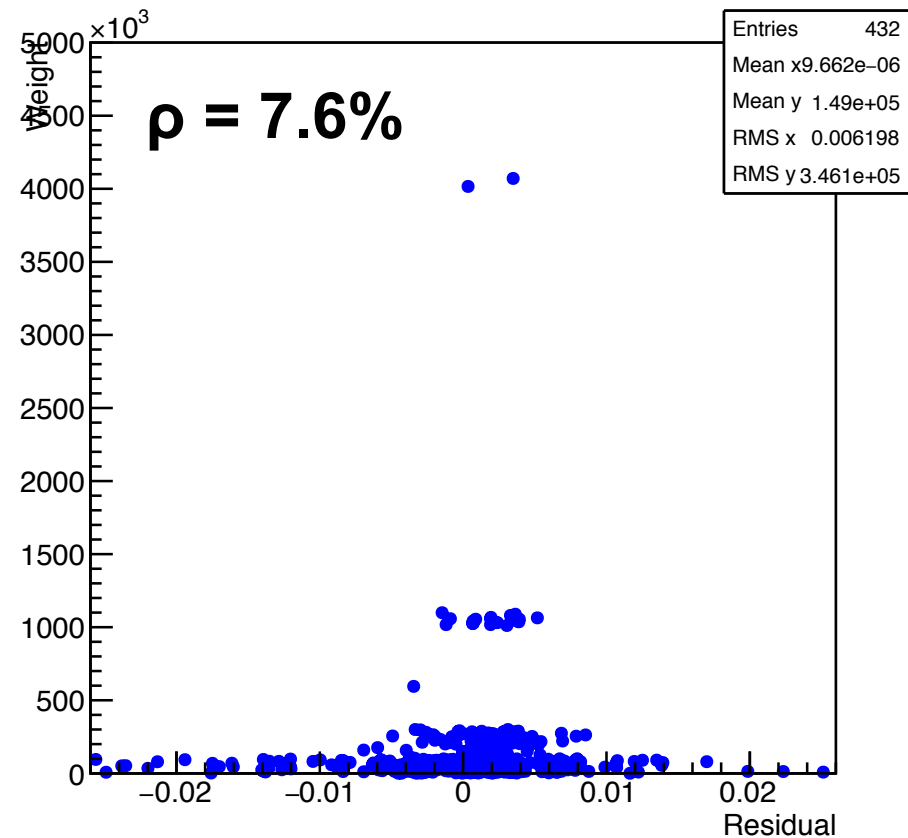

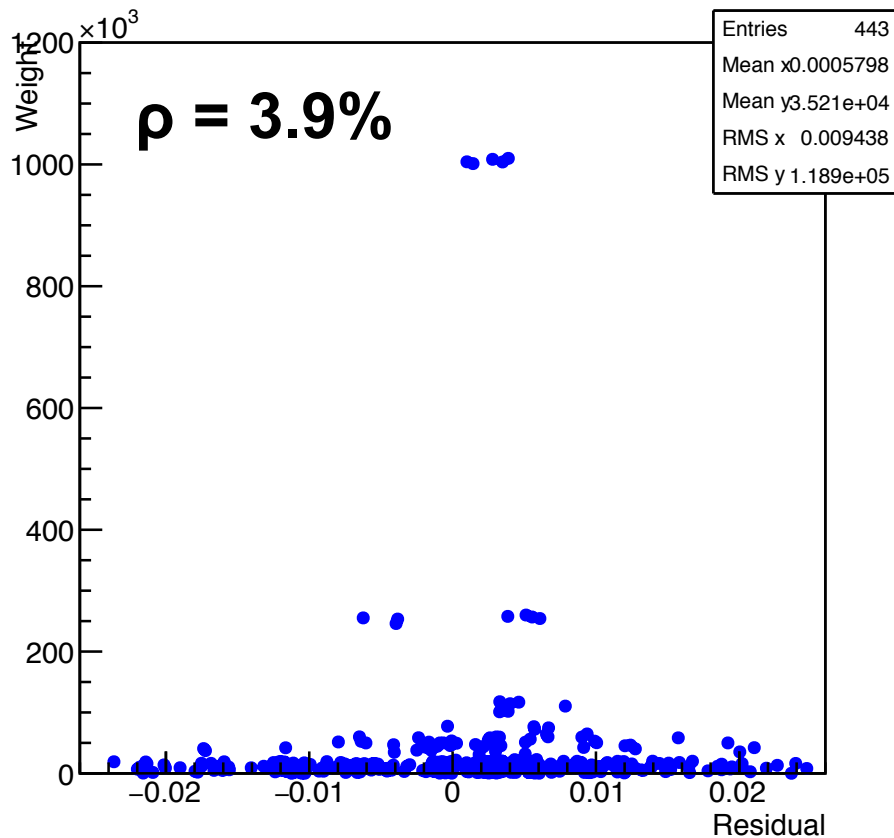

Correspondence: unweighted vs. weighted 2m measurements:

$$\text{Diff} = 0.00090 \pm 0.00030 \quad (3.04 \text{ sigma})$$

A correlation?

Plotted is the **measurement residuals** (measurement - mean) as a function of the **weight of the measurement** (i.e. $1/\text{uncertainty}^2$).

There is a slight correlation between the lengths and uncertainties quoted!

"Longer measurements have smaller errors!". Why? I don't know. But data shows it!

Fitting for a result

A completely different approach is to fit the RAW data, hence describing all data points instead of excluding some.

This approach is philosophically more clean, but certainly not easy!

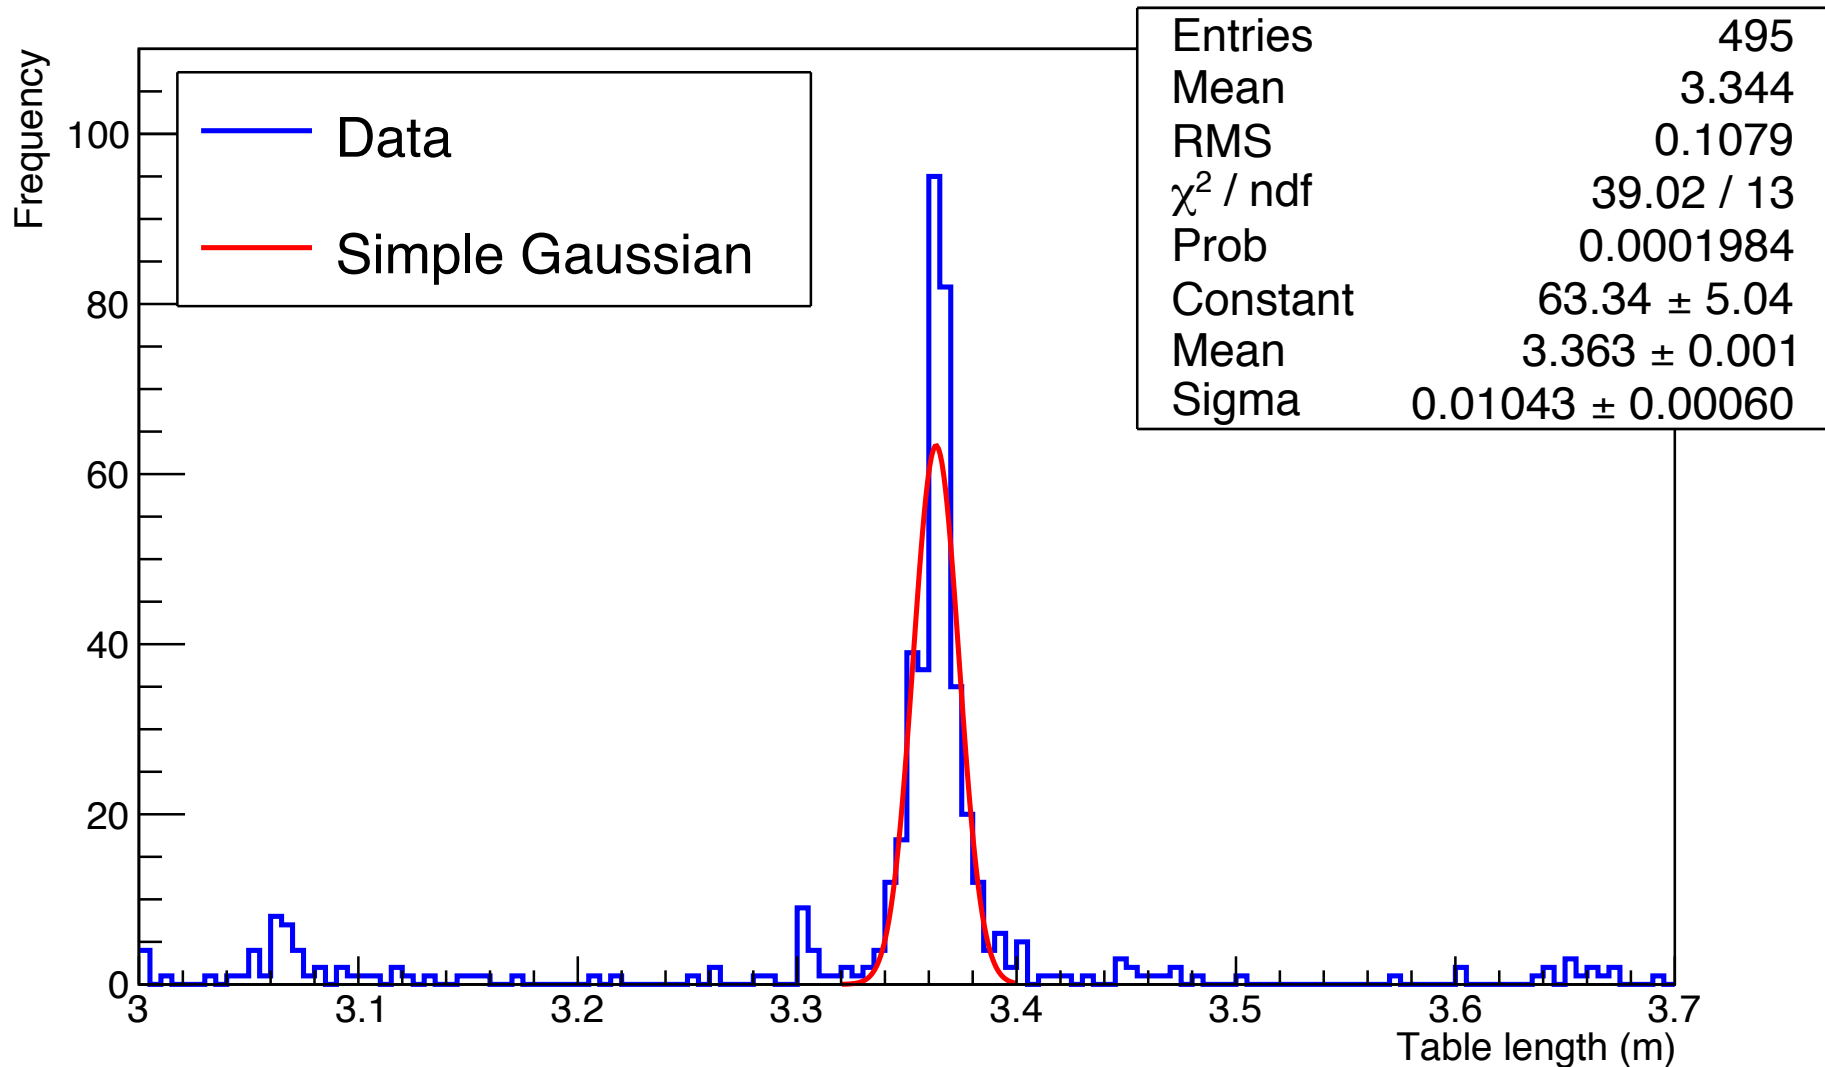

Challenges:

- Measurements has many different resolutions.
- There are several peaks in the data (30cm case).
- Some measurements are clearly rounded.

While all of these can be accommodated, it is still a challenge, at the following “fitting around” took me half and hour!

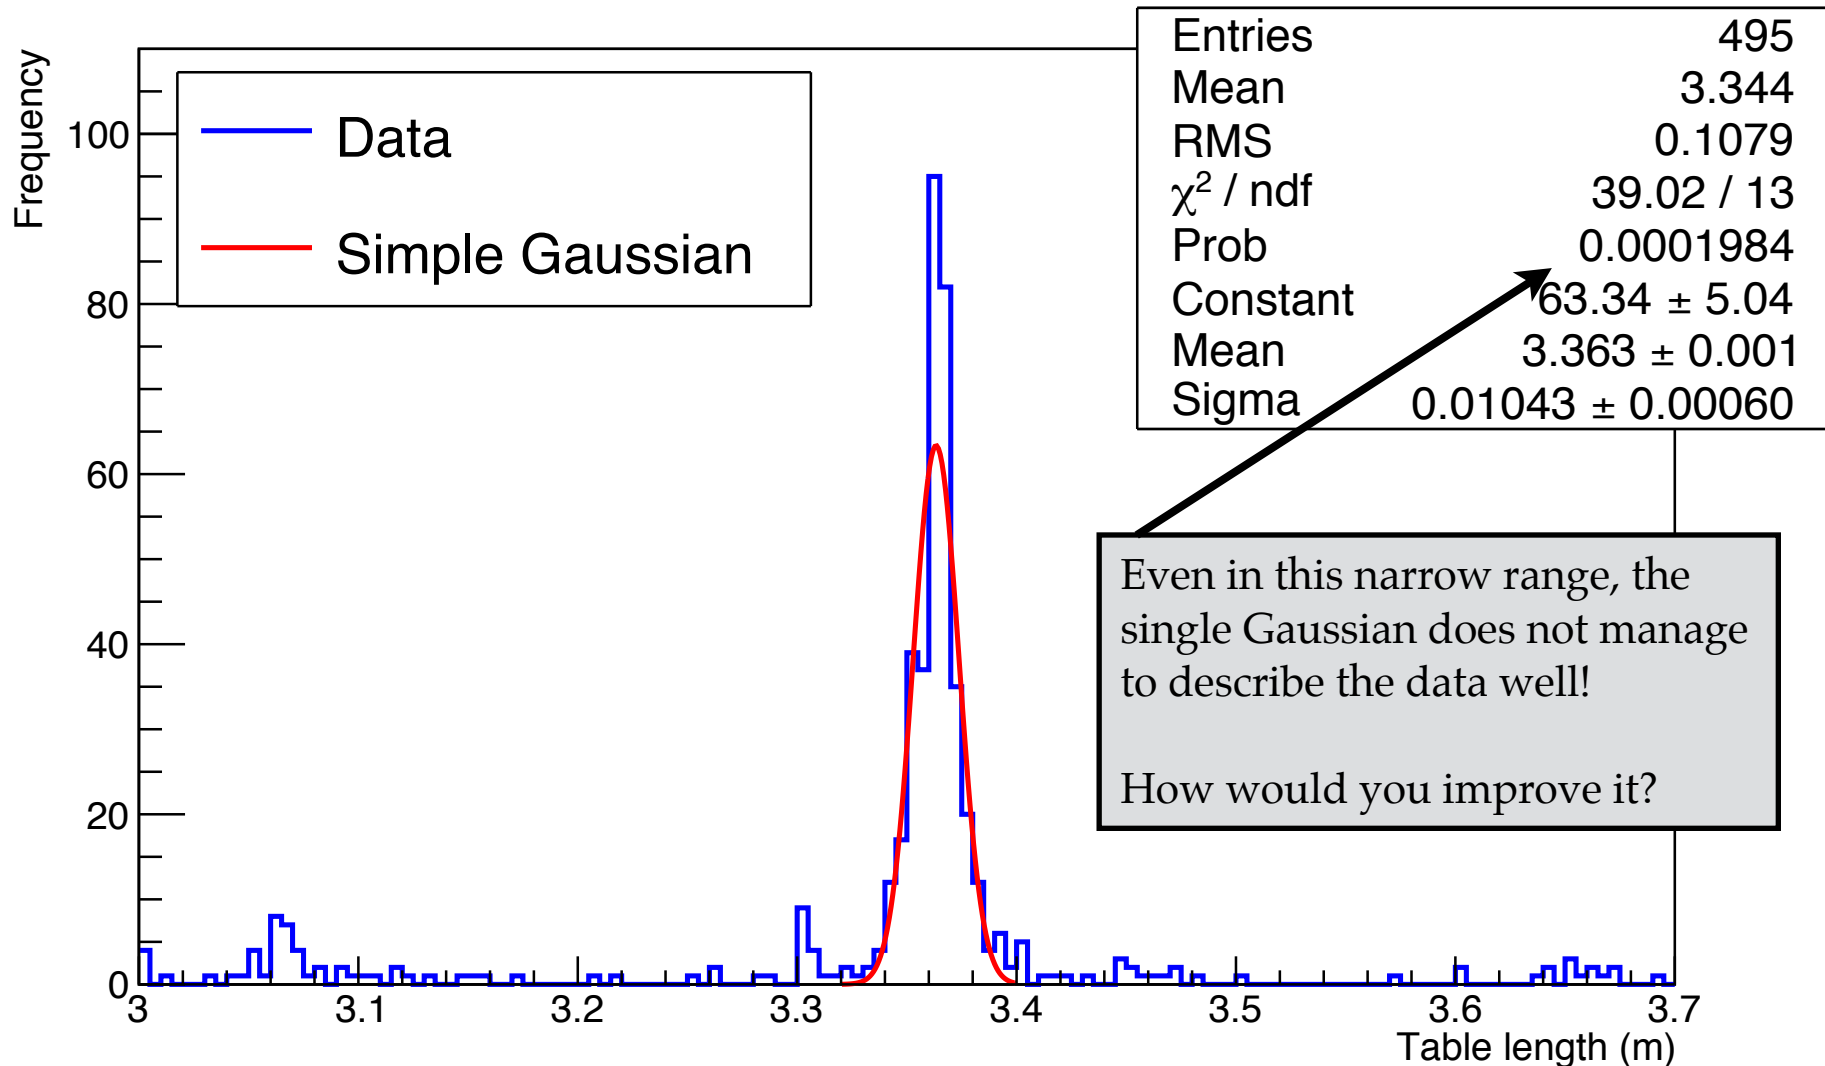

Fitting for a result

Your analyses

Your measurement results

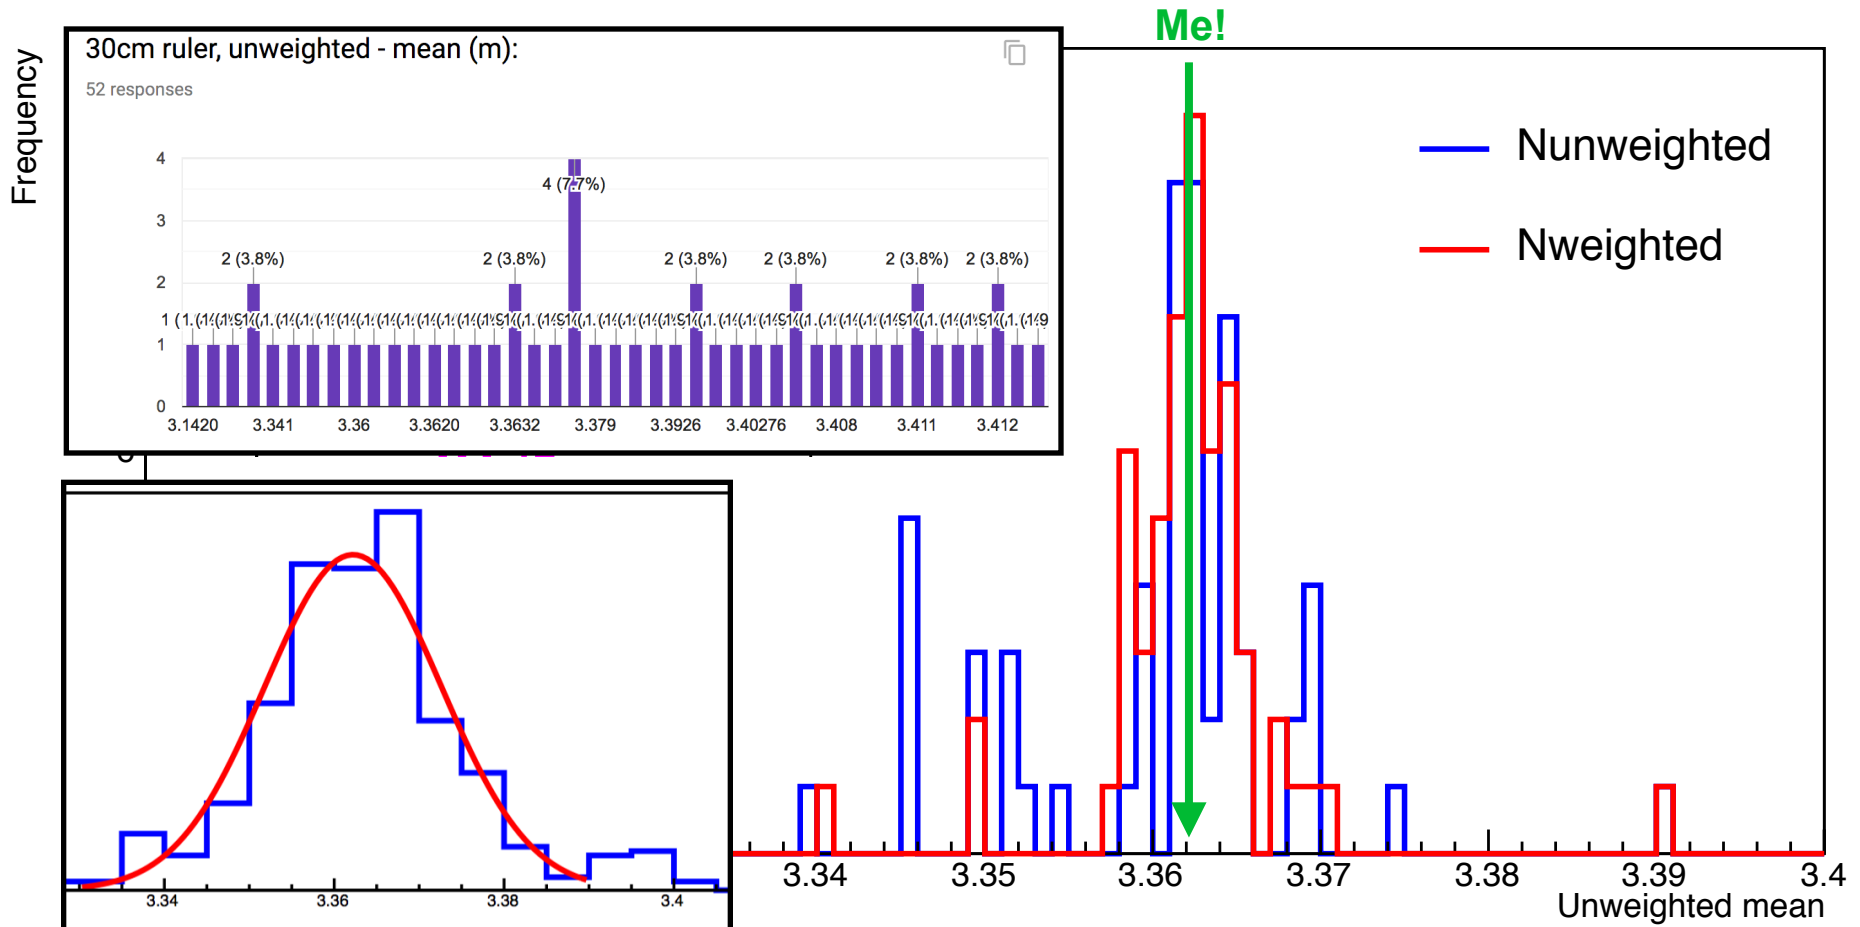

The number of measurements used varied quiet a bit.

But remember that the impact is only \sqrt{N} , and thus not that important!

Length results

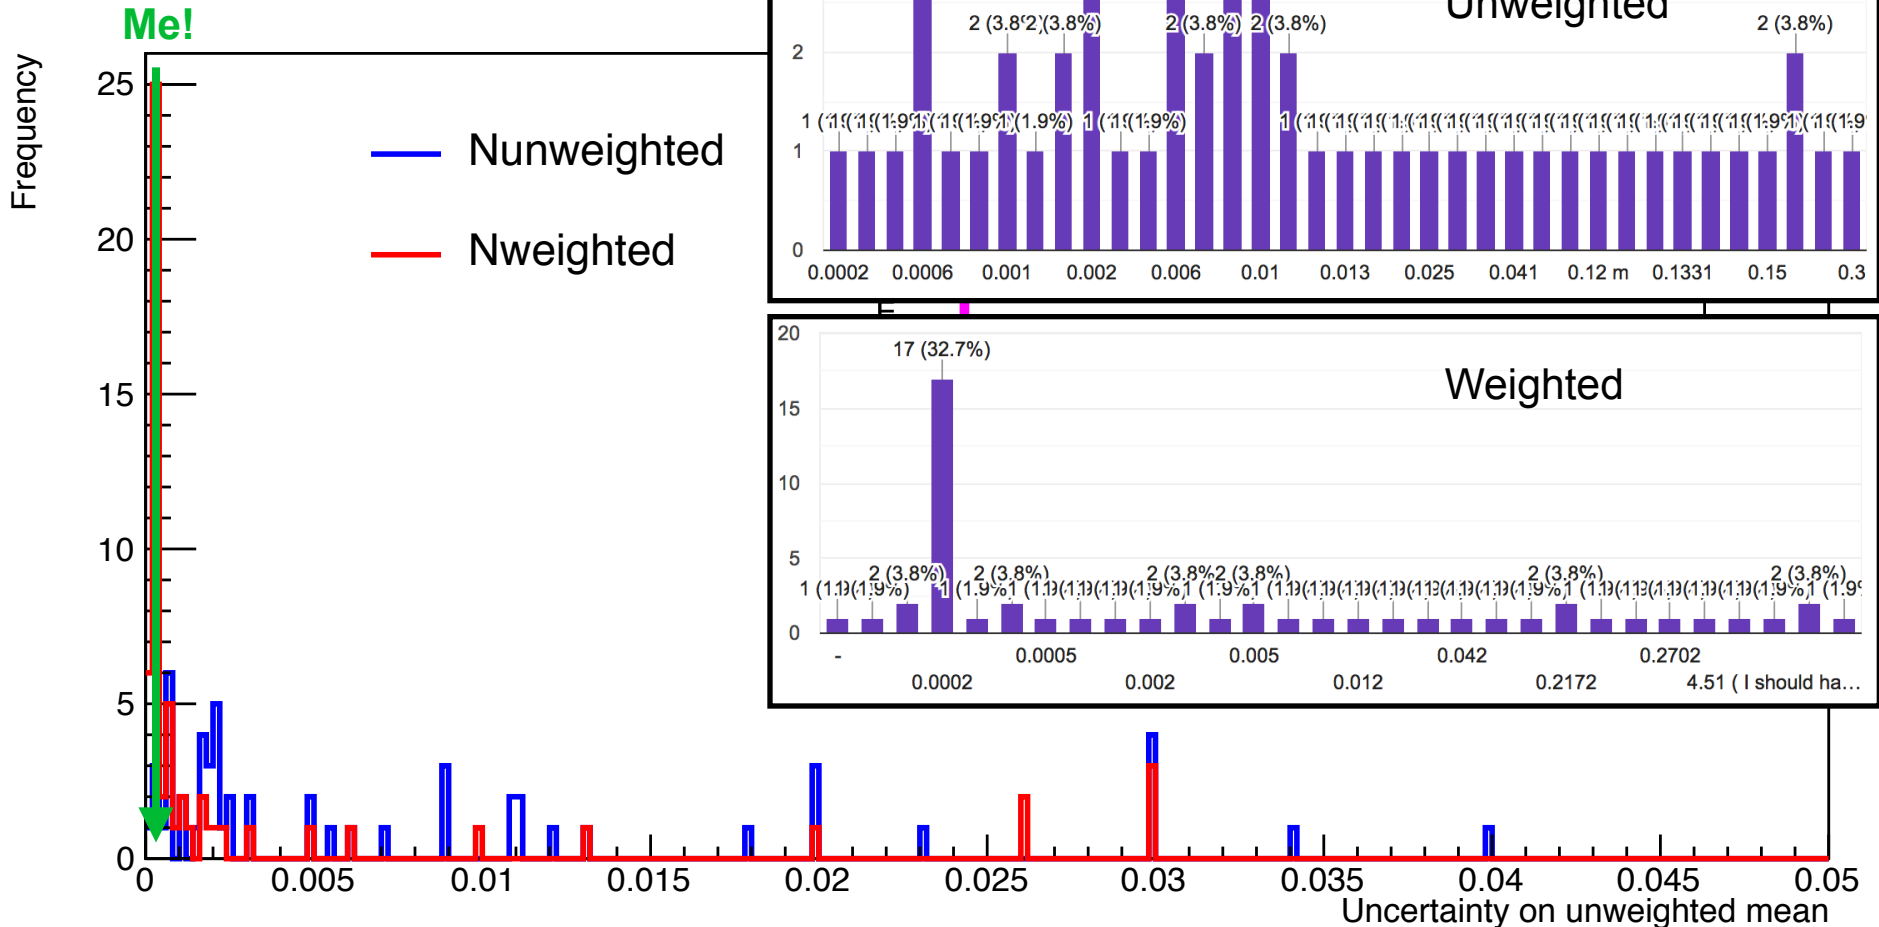

Results are relatively consistent... 80% of you get a value within 0.1% of "true"

I got: $L(\text{unweighted}) = 3.36227 \pm 0.00061 \text{ m}$, $L(\text{weighted}) = 3.36371 \pm 0.00035 \text{ m}$

Uncertainties

The uncertainties varied quite a bit - by more than a factor 100! Think about that.

I got: $L(\text{unweighted}) = 3.36227 \pm 0.00061 \text{ m}$, $L(\text{weighted}) = 3.36371 \pm 0.00035 \text{ m}$

Conclusions

Specifically on the analysis:

- Greatest improvement came from simply removing mis-measurements!
- Weighted result was a further improvement, but required good uncertainties.
- The uncertainties are accepted as “reasonable”, as they have good pull distributions, and improve the result.
- The 30cm and 2m results match, giving credibility to the stated precision.

More generally:

- What appears to be a trivial task, turns out to require some thought anyhow.
(Ask yourself how many fellow students would have been able to get a good result and error?)
- There were several choices to be made in the analysis:
 1. Which measurements to accept.
 2. Which uncertainties to accept.
 3. To correct or discard understood mis-measurements.
- All this can be solved with simple Python code.
